Das Hauptpatent hat angefangen am 10. August 1932.

Die Priorität der Anmeldung in den Niederlanden vom 4. November 1933 ist in Anspruch genommen.

Das Patent 652 752 beschreibt eine mit einem entlüfteten Raum umgebene, insbesondere zur Lichtausstrahlung dienende elektrische Entladungsröhre mit Dampf schwerflüchtiger Metalle, wie Natrium, bei der dieser Raum zwischen den Wänden einer doppelwandigen Hülle gebildet ist, die die Röhre mit einem Luft enthaltenden Zwischenraum umschließt. Dieser die Röhre umgebende, entlüftete Raum bildet einen Wärme isolierenden Mantel, der das Erreichen einer hohen Temperatur und eines hinreichenden Dampfdruckes in der Entladungsröhre erleichtert. Derartige Röhren sind bekannt.

Diese Anordnung hat u. a. den Vorteil, daß der Dampfdruck innerhalb der Röhre weniger abhängig ist von Änderungen der äußeren Atmosphäre, wie z. B. von Temperaturänderungen, Regenfall oder starkem Wind, als bei Verwendung einer die Entladungsröhre einschließenden einwandigen Hülle, bei der der Raum zwischen der Röhre und der Hülle entlüftet ist.

Die Erfindung hat bezweckt, die Abhängigkeit des Dampfdruckes innerhalb der Entladungsröhre von Änderungen der äußeren Atmosphäre weiter zu verringern.

Die Röhre und die doppelwandige Hülle werden erfindungsgemäß derart ausgebildet, daß beim Betrieb der der Sockelseite gegenüberliegende Teil des Entladungsraumes die niedrigste, in diesem Raum herrschende Temperatur erhält.

Es wurde nämlich gefunden, daß, wenn die kälteste, den Dampfdruck bestimmende Stelle des Entladungsraumes sich auf dem der Sockelseite gegenüberliegenden Teil der Wand des Entladungsraumes befindet, die durch Änderungen der Umgebungstemperatur herbeigeführten Änderungen der Temperatur der kältesten Stelle kleiner sind, als wenn ein näher beim Sockel befindlicher Teil der Wand des Entladungsraumes die kälteste Stelle bildet.

Diese geringere Empfindlichkeit der Temperatur eines dem Sockelende gegenüber-

6.3 Communications and Recording Technologies

German-speaking creators invented and demonstrated communications and recording technologies that revolutionized the world:

6.3.1. Telegraphs

6.3.2. Telephones

6.3.3. Radio

6.3.4. Mobile telephone systems

6.3.5. Optical communications systems

6.3.6. Disc phonograph records and players

6.3.7. Magnetic tape recording

6.3.8. Motion picture cameras and projectors

6.3.9. Television

6.3.10. Video telephone system

6.3.11. Scanners, facsimile (fax) machines, and printers

6.3.12. Photocopiers

6.3.13. Optical discs and digital file formats

Unfortunately, the modern world often does not attribute these inventions to their actual creators.

6.3.1 Telegraphs

Carl Friedrich Gauss (German states, 1777–1855) and Wilhelm Weber (German, 1804–1891), shown in Fig. 6.21, worked out the laws of magnetism and electromagnetism. Using those, they invented and demonstrated the world's first electric (electromagnetic or electromechanical) telegraph in 1833, five years before Samuel Morse, whose work became much better known outside the German-speaking world [Dunnington 1955]. (See also pp. 740, 793, 828, and 858.)

In a 20 November 1833 letter from Carl Friedrich Gauss to Heinrich Olbers, Gauss described the design and successful operation of his telegraph [English translation by Guy Waldo Dunnington, in Dunnington 1955, p. 147]:

> I don't remember my having made any previous mention to you of an astonishing piece of mechanism that we have devised. It consists of a galvanic circuit conducted through wires stretched through the air over the houses up to the steeple of St. John's Church and down again, and connecting the observatory with the physics laboratory, which is under the direction of Weber. The entire length of wire may be computed at about eight thousand feet; both ends of the wire are connected with a multiplicator, the one at my end consisting of 170, that in Weber's laboratory of 50, coils of wire each wound around a one-pound magnet suspended according to a method which I have devised. By a simple contrivance—which I have named a commutator—I can reverse

> the current instantaneously. Carefully operating my voltaic pile, I can cause so violent a motion of the needle in the laboratory to take place that it strikes a bell, the sound of which is audible in the adjoining room. This serves merely as an amusement. Our aim is to display the movements with the utmost accuracy. We have already made use of this apparatus for telegraphic experiments, which have resulted successfully in the transmission of entire words and small phrases. This method of telegraphing has the advantage of being quite independent of either daytime or weather; the ones who receive it remain in their rooms, and if they desire it, with the shutters drawn. The employment of sufficiently stout wires, I feel convinced, would enable us to telegraph with but a single tap from Göttingen to Hanover, or from Hanover to Bremen.

Dunnington summarized further details about the history of the Gauss-Weber telegraph [Dunnington 1955, pp. 147–148, 150]:

> Gauss gave first public notice of the telegraph in the *Göttingische gelehrte Anzeigen*, issue of August 9, 1834. He gives detailed information about the "great galvanic circuit" between the physics laboratory and the observatory, to which the new magnetic observatory was connected, and emphasizes that this "unique setup" is due to Weber. The two had begun their electrical measurements on October 21, 1832. Gauss ordered magnetometers of varying size, from which he proceeded to larger magnets, and thus a number of galvanometers of varying size and construction came into being, although we do not know which ones were finally used in telegraphing. They were all to be used for this purpose, but the two scientists realized that the apparatus with the smallest magnets was best adapted for telegraphing on account of the magnets' small period of oscillation.
>
> It is reported that the first words sent on the telegraph were: *Michelmann kommt.* Michelmann was a servant who ran errands for Gauss and Weber. At first individual words were sent, and then complete sentences. The telegraph was operated once in the presence of the Duke of Cambridge, who seemed to take special interest in it.
>
> Weber's correspondence with the city council in April and May, 1833, gave exact information about the purpose and date of origin of the telegraph. At first Weber had used thin copper wire for the lines, which, however, did not stand up very well and had to be replaced by stronger wire. Even the latter did not resist weathering and was replaced by soft steel wire of one-millimeter strength. The lines existed until 1845, when they were destroyed by lightning on December 16. [...]
>
> The success of Gauss and Weber with their telegraph aroused great attention at that time, at least in Germany. Steps were under way to use it on the railroad. Gauss and Weber both wrote memoranda on the subject to the directorate of the Leipzig-Dresden railroad then under construction.

In 1846, Werner von Siemens (German, 1816–1892, Fig. 6.22) created more sophisticated telegraphs that could point to individual letters [Bähr 2016; von Siemens 1895]. Von Siemens also invented and sold a number of other important electrical components and systems (p. 944). Backed by a large industry and using more advanced designs, the von Siemens telegraphy systems overtook the demonstrations and proposals of Gauss and Weber. Werner von Siemens and Carl Wilhelm Siemens (German, 1823–1883), one of his younger brothers, designed and produced telegraph networks that were used in Europe and worldwide.

6.3.2 Telephones

Johann Philipp Reis (German, 1834–1874) invented and successfully demonstrated the world's first microphone, speaker, and telephone in 1860 (Fig. 6.23). He then publicized and sought funding to improve his telephone. Reis demonstrated this working telephone system 16 years before Alexander Graham Bell's version in 1876, yet nowadays Reis is virtually unknown in the non-German-speaking world, and Bell is widely viewed as the inventor of the telephone. In 2003, BBC News confirmed that "Bell 'did not invent telephone'" [http://news.bbc.co.uk/2/hi/science/nature/3253174.stm]:

> Claims that a German scientist invented the telephone 15 years before Alexander Graham Bell are supported by evidence from newly surfaced archive papers.
>
> Successful tests on a German device manufactured in 1863 were covered up to maintain the Scot's reputation, the previously unseen files have revealed.
>
> They show the "Telephon", developed by German research scientist Philipp Reis, could transmit and receive speech.
>
> It is alleged UK businessman Sir Frank Gill was behind the cover-up.
>
> The evidence is contained in files from the archives of the Science Museum in London.
>
> The documents were rediscovered in October by the museum's curator of communications, John Liffen.
>
> Gill was chairman of Standard Telephones and Cables (STC), the company that conducted the tests on Reis's device.
>
> The company was at the time bidding for a contract from the American Telephone and Telegraph Company, which evolved from the Bell Company.
>
> Gill thought that if word got out of the test results, it would scupper STC's chances of winning the contract.
>
> Some researchers have argued for many years that Reis beat Bell to the invention of the telephone. The archived documents seem to support their claims.
>
> A memo, dated 18 March 1947, from Gerald Garratt, a predecessor of Mr Liffen's, show STC's reports on Reis's device were given to him under the strict condition that they would never be publicly referred to or published without permission.
>
> STC then became anxious to retrieve the documents. In a subsequent letter, Garratt wrote: "I am left with the thought that there is something so secret about [the documents] as to be a matter of first class historic interest.
>
> "You must know as well as I the old controversy: 'Did Bell invent the telephone?' and I have here an unpublished manuscript of over 400 pages which proves pretty conclusively that he didn't.
>
> "Does your anxiety to retrieve these reports rather suggest that you agree?"

Werner von Siemens (German, 1816–1892, Fig. 6.22) invented improved speakers.

6.3.3 Radio

In 1888, Heinrich Hertz (German, 1857–1894) produced, detected, and measured electromagnetic waves, specifically radio waves, making him also the true original inventor of radio transmitters and receivers (Fig. 6.24). Unfortunately Hertz died very young; otherwise he would likely have played even more of a role (and been recognized much more) in the early development of radio technology. Because Hertz died before the first Nobel Prizes were awarded in 1901, he was not eligible for the Nobel; nonetheless, the Nobel committee publicly praised his discoveries when they awarded other scientists (see below and p. 859).

Nikola Tesla (Serbo-Croatian, educated in Austria, 1856–1943) publicly demonstrated a radio transmitter and receiver in 1891, and a tunable transmitter and receiver in 1893 in St. Louis (Fig. 6.25). Tesla biographer Margaret Cheney listed some of the key technical features of Tesla's 1893 public demonstration [Cheney 1981, p. 69]:

> Although the St. Louis demonstration was no "message sent 'round the world" as Tesla would doubtless of course have preferred it to be, he had nevertheless demonstrated all the fundamental principles of modern radio: 1. an antenna or aerial wire; 2. a ground connection; 3. an aerial-ground circuit containing inductance and capacity; 4. adjustable inductance and capacity (for tuning); 5. sending and receiving sets tuned to resonance with each other; and 6. electronic tube detectors.

Tesla's 1893 lecture was published and translated around the world. Apparently it was the direct inspiration for Guglielmo Marconi (Italian, 1874–1937) to repeat part of Tesla's experiments a few years later, albeit in a much cruder and less effective fashion [Cheney 1981, p. 69]. A series of court cases over radio patents ultimately proved that Tesla's public disclosures, publications, and discoveries predated and directly informed Marconi's claims [Cheney 1981, p. 176–184; Cheney and Uth 1999, pp. 67–73]. Yet while Tesla continued working on his inventions, Marconi went on a lengthy public tour of self-promotion in Europe. As a result, Marconi was awarded a Nobel Prize for his "discovery," Tesla was not, and Marconi has been erroneously considered worldwide to be the inventor of radio.

Tesla further showed that radio waves transmit not only signals but large amounts of power over considerable distances [Cheney 1981; Cheney and Uth 1999; Tesla 1893, 1904, 1919, 1940]. Tesla also demonstrated a radio-controlled boat in 1898 (p. 1207) and invented many other electrical devices (p. 954).

Beginning in 1897, Karl Ferdinand Braun (German, 1850–1918) developed improved radio transmitters and receivers (Fig. 6.26), as well as phased array antennas. He also invented semiconductor diodes (p. 1045), cathode ray tubes, and oscilloscopes (p. 1000). For his work developing and improving radio technology, he won the Nobel Prize in Physics in 1909. H. Hildebrand, President of the Royal Swedish Academy of Sciences, praised both Braun's innovations and the earlier discoveries by Hertz [https://www.nobelprize.org/prizes/physics/1909/ceremony-speech/]:

> [I]t was Hertz who through his classical experiments showed that the new ideas as to the nature of electricity and light had a real basis in fact. To be sure, it was already well known before Hertz's time, that a capacitor charged with electricity can under certain

> circumstances discharge itself oscillatorily, that is to say, by electric currents passing to and fro. Hertz, however, was the first to demonstrate that the effects of these currents propagate themselves in space with the velocity of light, thereby producing a wave motion having all the distinguishing characteristics of light. This discovery—perhaps the greatest in the field of physics throughout the last half-century—was made in 1888. It forms the foundation, not only for modern science of electricity, but also for wireless telegraphy. But it was still a great step from laboratory trials in miniature where the electrical waves could be traced over but a small number of metres, to the transmission of signals over great distances. [...]
>
> The electrical oscillations sent out from the transmitting station were relatively weak and consisted of wave-series following each other, of which the amplitude rapidly fell-so-called "damped oscillations". A result of this was that the waves had a very weak effect at the receiving station, with the further result that waves from various other transmitting stations readily interfered, thus acting disturbing at the receiving station. It is due above all to the inspired work of Professor Ferdinand Braun that this unsatisfactory state of affairs was overcome. Braun made a modification in the layout of the circuit for the despatch of electrical waves so that it was possible to produce intense waves with very little damping. It was only through this that the so-called "long-distance telegraphy" became possible, where the oscillations from the transmitting station, as a result of resonance, could exert the maximum possible effect upon the receiving station. The further advantage was obtained that in the main only waves of the frequency used by the transmitting station were effective at the receiving station. It is only through the introduction of these improvements that the magnificent results in the use of wireless telegraphy have been attained in recent times.

Adolf Slaby (German, 1849–1913) and Georg von Arco (German, 1869–1940), shown in Fig. 6.27, developed radio systems from 1897 onward. They founded and ran radio research and development departments first at AEG and then at Telefunken.

By harnessing radio waves, Christian Hülsmeyer (German, 1881–1957) invented and demonstrated radar in 1903 (p. 1219). He also patented a radio remote control system in 1904.

Ernst Walter Ruhmer (German, 1878–1913) invented a number of electrical communications devices, collaborating with Salomon Kalischer (German, 1845–1924) and Adolf Pieper (German, 18??–19??) on some of them. In 1904, Ruhmer demonstrated a radiotelephone transmitter and receiver capable of sending the first intelligible voice signals (Fig. 6.28).

Vacuum tube technology evolved from the work of a series of German-speaking scientists, including Julius Plücker (German states, 1801–1868), Heinrich Geissler (German, 1814–1879), Johann Hittorf (German, 1824–1914), Eugen Goldstein (German, 1850–1930), Arthur Wehnelt (German, 1871–1944), and others. See Fig. 6.17.

In 1906, Robert von Lieben (Austrian, 1878–1913), Eugen Reisz (Austrian, 18??–19??), and Siegmund Strauss (Austrian, 18??–19??) invented and demonstrated the triode vacuum tube amplifier (Fig. 6.29). It greatly improved the performance of radio circuits.

No later than 1912, Alexander Meißner (Austrian, 1883–1958) invented, demonstrated, and patented the first modulated, amplified radio systems for high-quality transmission of voices and music. See Fig. 6.30.

Eugen Nesper (German, 1879–1961, Fig. 6.31) conducted experiments with radio transmitters and receivers from 1897 onward. Early in his career, he worked with Adolf Slaby and Georg von Arco. Among other accomplishments, he developed and demonstrated a radio receiver with a powerful seven-tube amplifier in 1923.

Hans Bredow (German, 1879–1959, Fig. 6.31) worked with electrical systems, especially radio, from 1900 onward. Throughout his long career, he was a strong proponent of public radio broadcasting systems in Germany.

6.3.4 Mobile Telephone Systems

By combining telephone and radio technologies, German-speaking scientists invented and commercialized the world's first mobile telephone system. As shown in Fig. 6.32, such mobile phones consisted of telephones and compact radio transmitter boxes, and were installed in German passenger trains (the system was called Zugpostfunk or Zugtelefon). Transmitter/receiver towers near the track connected the train mobile phones to the normal wired telephone network, allowing passengers on trains to call (or receive calls from) people who either were not on trains or were on other trains. Development of the system began during World War I, and the service was commercialized and in service by January 1926. After World War II, the United States copied this mobile telephone system and installed it in U.S. trains. Ultimately mobile telephone technology was miniaturized using microelectronics components and methods that had also been invented in the German-speaking world (Section 6.5 and Appendix B).

6.3.5 Optical Communications Systems

German-speaking scientists also developed systems for transmitting and receiving voices and data via light signals. See p. 1131.

Kathodenstrahlenrelais.

Patentiert im Deutschen Reiche vom 4. März 1906 ab.

Die vorliegende Erfindung bezweckt, mittels Stromschwankungen kleiner Energie solche von großer Energie auszulösen, wobei Frequenz und Kurvenform der ausgelösten Stromschwankungen denen der auslösenden entsprechen.

Die diesem Zweck entsprechende Relaisanordnung ermöglicht es, durch die Wahl der Stärke des durch eine Entladungsröhre fließenden Stromes die im beeinflussenden Stromkreise vorhandenen Energiemengen zu multiplizieren und eignet sich daher für alle Fälle, wo eine derartige Multiplikation innerhalb weiter Grenzen gefordert wird. Insbesondere für manche Probleme der Telephonie (Übertragung der Sprache auf große Entfernungen, Kabeltelephonie, drahtlose Telephonie, Verstärkung der Sprach- und Musikübertragung usw.) kann die Anwendung dieses Relais von Vorteil sein; ferner auch für manches Problem der Fernphotographie, Phonographie usw.

Um diesen Zweck zu erreichen, wird die von Wehnelt gefundene Eigenschaft glühender Metalloxyde benutzt, im Vakuum als Kathoden bei verhältnismäßig niedrigen Potentialen (etwa 200 Volt) Kathodenstrahlen zu emittieren. Die so erzeugten Kathodenstrahlen besitzen geringe Geschwindigkeit und werden daher schon von schwachen magnetischen oder elektrostatischen Feldern stark abgelenkt. Diese Kathodenstrahlen befinden sich hier in dem zu beeinflussenden Stromkreise und werden durch die schwachen Stromschwankungen eines zweiten unabhängigen Stromkreises magnetisch oder elektrostatisch verschieden stark abgelenkt. Diese Ablenkungen bewirken nun durch die Wahl der im folgenden beschriebenen Anordnung die gewünschten starken Schwankungen, die im Stromkreis der Kathodenröhre erfolgen.

Letztere besteht nun, wie aus der Zeichnung ersichtlich ist, aus der hoch evakuierten Glasröhre *r*, in welche die zur Erhitzung der Kathode *k* erforderlichen Stromzuführungsdrähte $\mathfrak{z}_1$ und $\mathfrak{z}_2$ eingeschmolzen sind.

Die Kathode *k* besteht aus einem durch den elektrischen Strom heizbaren, hitzebeständigen Körper, dem die Form eines Hohlspiegels gegeben wird. Die dem Metallkörper *f* zugekehrte Oberfläche dieses Hohlspiegels *k* ist mit einer dünnen Schicht eines nach Wehnelt wirksamen Metalloxydes (*Ca O*, *Ba O* usw.) überzogen. Wird nun das negative Potential der Stromquelle *b* an den beispielsweise durch die Batterie b_1 elektrisch geheizten Hohlspiegel *k* angelegt, so entsendet derselbe Kathodenstrahlen, die sich in einem Brennpunkte (oder in einer Brennlinie) schneiden. Wie man sieht, fällt dieser Brennpunkt in die Öffnung *o* des Faradayschen Hohlzylinders *f*. Durch diese Öffnung gelangen die Strahlen weiter in den inneren Hohlzylinder f_1. Beide Hohlzylinder sind konzentrisch, voneinander elektrisch isoliert und durch die eingeschmolzenen Zuführungsdrähte $\mathfrak{z}_3$ $\mathfrak{z}_4$ nach außen abgeleitet. Wie die Schaltung zeigt, führt $\mathfrak{z}_4$ (unter Vorschaltung eines passenden Widerstandes *w*) direkt, $\mathfrak{z}_3$ unter Zwischenschaltung eines für Strom-

Einrichtung zur Erzeugung elektrischer Schwingungen.

Patentiert im Deutschen Reiche vom 10. April 1913 ab.

Die vorliegende Erfindung betrifft eine Einrichtung zur Erzeugung elektrischer Schwingungen, die darauf beruht, daß ein oder mehrere Schwingungskreise mit einem elektrischen Relais, dessen die Relaiswirkung ausübendes Mittel aus Kathodenstrahlen oder einem ionisierenden Gas o. dgl. besteht, so verbunden wird, daß die in den Schwingungskreisen durch irgendwelche Stöße oder andere Mittel hervorgerufenen Anfangsschwingungen dem Relais zugeführt werden und die von diesem verstärkten Ströme wieder auf die Schwingungskreise einwirken, wodurch die Amplitude der Eigenschwingung der Kreise erhöht wird. Da der wirksame Bestandteil dieser Relais im Gegensatz zu mechanisch arbeitenden keine Masse besitzt, so ist es gerade mit diesem Relais möglich, elektrische Schwingungen bis zu den höchsten Frequenzen in der angegebenen Einrichtung zu erzeugen und da die Frequenz der Schwingungen nur durch die Eigenschwingung des Schwingungssystems bedingt ist, und im Relais andererseits keine störenden Einflüsse sich geltend machen, so erzielt man mit dieser Einrichtung zum ersten Mal ungedämpfte Schwingungen von absolut konstanter Schwingungszahl und Amplitude.

Eine z. B. für diesen Zweck sehr geeignete Form dieser Relais besteht aus einem ganz oder teilweise evakuierten oder mit Gasen oder Dämpfen unter geringem Druck gefüllten Glasgefäß, das eine erhitzte Kathode und eine oder mehrere Anoden enthält. Die von der Kathode ausgehenden Kathodenstrahlen sind entweder selbst das wirksame Agens oder bewirken eine Ionisation des Gases, so daß ein dauernder Stromweg im Relais hergestellt wird. Die zu verstärkenden Ströme können der erhitzten Kathode und einer Hilfsanode (Primärseite des Relais) zugeführt werden. Die verstärkten Ströme treten dann in dem über die Kathode und Hauptanode (Sekundärseite) geführten Stromkreis auf, wobei die vermehrte Energie dieser Ströme aus der den Dauerstrom liefernden Stromquelle entsteht.

Eine Ausführungsform der Schaltung unter Zugrundelegung eines solchen Relais ist in der Figur dargestellt.

1 ist das Kathodenstrahlrelais, das die von der Batterie 2 geheitzte Kathode 3 und die Anode 4 enthält. 5 ist eine Hilfselektrode, die mit der Kathode 3 über die Kopplungsspule 6 leitend verbunden ist. 7 ist ein Schwingungskreis, der aus dem Kondensator 8 und den beiden Selbstinduktionen 9 und 10 besteht. Dieser Schwingungskreis 7 steht einerseits mit der Anode 4 und andererseits, über die Stromquelle 11, mit der Kathode 3 in Verbindung. Der Schwingungskreis 7 ist also sowohl mit der Primär-, wie mit der Sekundärstrecke des Relais gekoppelt. 12 ist eine Drosselspule, die gemeinsam mit der Kapazität 13 erforderlich ist, sofern als Stromquelle 11 nicht eine Batterie, sondern eine Maschine zur Speisung des Entladungsrohres 1 benutzt wird. In diesem Fall dient die Einrichtung dazu, die störenden Wirkungen des

6.3.6 Disc Phonograph Records and Players

Emil(e) Berliner (German, 1851–1929) was educated in Germany and then moved to the United States. In 1886, he invented disc phonograph records and the corresponding player, which he called the Gramophone (Fig. 6.33). Earlier phonographs had used cylinders made of wax, which were quite cumbersome in shape and also very fragile and temperature sensitive. Berliner's flat discs made of hard rubber were durable recordings that could be easily stored, stacked, played, and flipped. Berliner also developed improved microphones, acoustic tile, and an improved loom for producing cloth, and he experimented with proto-helicopters and autogyros (p. 1804).

6.3.7 Magnetic Tape Recording

Fritz Pfleumer (Austrian, 1881–1945), Walter Weber (German, 1907–1944), and Hans-Joachim von Braunmühl (German, 1900–1980) developed magnetic plastic tape recorders, dubbed the Magnetophon, with the first demonstration in 1927 [Albert 2014]. See Fig. 6.34. Weber and von Braunmühl also invented improved designs for microphones.

German-speaking creators also developed a magnetic tape recorder that used steel tape instead of plastic tape. In 1930, Kurt Stille (German, 1873–1957) and Ludwig Blattner (German, 1881–1935) invented the Blattnerphone magnetic steel tape recorder, shown in Fig. 6.35. However, the advantages of the plastic tape soon won out.

Magnetic tape recording technology was transferred to other countries after World War II. For example, BIOS 951, *The Magnetophon Sound Recording and Reproducing System*, reported:

> This report describes a system for the recording and reproduction of sound, making use of the well-known magnetic principle, which has been developed in Germany both before and during the war. During the war an improvement in performance has been achieved and the quality of reproduction of speech and music now obtainable by means of this system is of a high order and, it is claimed, consistently better than that achieved with other systems.

There were a number of other postwar Allied reports on German magnetic tape recorders, such as BIOS 1379, *Plastics in German Sound Recording Systems*, and FIAT 705, *High Frequency Magnetophone Magnetic Sound Recorders*. In addition to the reports, many magnetic recorders and reels of tape were seized and later copied by Allied countries (Figs. 6.36–6.37). For example, a U.S. Army officer, John T. "Jack" Mullin, confiscated several German Magnetophon units, shipped them to a private address in the United States, and then presented their technology to potential customers and investors as his own invention. Mullin became much more famous and wealthy than the actual German and Austrian inventors, and he was part of a pattern, not an isolated case.

In 1963, small reels of magnetic audio tape were packaged and marketed as "compact cassette tapes" by Philips Eindhoven, and that format was dominant worldwide for over three decades. (For more information on Philips Eindhoven, see p. 1019.)

The Magnetophon is just one example of the revolutionary magnetic recording technologies for audio, video, and data that were invented and perfected in Germany, then transferred to Allied countries in 1945 and used worldwide for decades [Gimbel 1990]. Gunter Guttwein (German, 1906–1978) also developed magnetic recording and magnetic memory technologies in Germany, and brought those to the U.S. Army's Fort Monmouth electronics laboratory after World War II [Fort Monmouth Historical Office 2008].

Magnecord
} Signal Corps

The discovery of the Magnetophone, an extremely high-fidelity device developed by the Germans as a result of wartime research, has aroused great interest in this country and gives excellent promise of revolutionizing the American sound recording and reproducing industry.

The machine uses a metallized plastic tape one-quarter of an inch in width instead of the usual flat disc or cylinder. Sound recording and reproduction is accomplished by magnetization of the metallized plastic tape. Since there is no needle wear involved in the process, there is no noise or scratch and no record wear. Also, a reel of tape will record from twenty to sixty minutes of sound; and proper synchronization of the operation of the equipment can be employed where operation of several hours duration is necessary for continuity purposes. The fact that a reel of tape will cost approximately fifty cents indicates the potential economies inherent in the development.

Indications are, as a result of industry interest in this development, that it will revolutionize not only the sound recording and reproducing equipment industry but also, because of its extremely low noise ratio and program continuity characteristics, most of the radio programs will consist of reproductions rather than direct broadcast transmissions as is the case at present. The use of reproduced rather than direct radio program broadcasts will provide for the more flexible and consequently more economical radio program production than can be accomplished at present on a direct program broadcast basis. This feature alone will be of inestimable value for the recording, reproduction and radio transmission of complete symphonic orchestrations of sufficiently high fidelity that the fact that reproduction is being employed will be impossible for listeners to detect.

The extent of industry interest in this development is indicated by the fact that Audio Products Company of New York City is manufacturing the tape, and the Rangertone Company of Newark, New Jersey is manufacturing the machine. The "know-how" used in the manufacture of these items was obtained directly from Report No. PB-12659 published by the Office of Technical Services of the Department of Commerce.

Shown below are samples of the tape produced in Germany and that manufactured in this country:

German Tape   American Tape

6.3.8 Motion Picture Cameras and Projectors

As shown on p. 634, the brothers Max Skladanowsky (German, 1863–1939) and Emil Skladanowsky (German, 1866–1945) created the Bioscop motion picture camera and projector in 1892 and presented the first public films in 1895.

Methods of recording audio tracks on visual film reels were developed by Josef Benedict Engl (German, 1893–1942), Joseph Massolle (German, 1889–1957), Hans von Ohain (German, 1911–1998), and Hans Vogt (German, 1890–1979).

6.3.9 Television

In the English-speaking world, television is generally regarded as an invention that originated with experiments before World War II by Philo Farnsworth (U.S., 1906–1971), Vladimir Zworykin (Russian but worked in the United States, 1888–1982), and John Logie Baird (Scottish, 1888–1946), and that led to the first major television systems and programs in the 1950s. While those scientists and events were indeed part of the history of television, scientists from the great German-speaking world were responsible for most of the key steps in the development of television, from the earliest experiments through the world's most advanced television systems in 1945 and beyond.

In the first important step toward television development, Julius Plücker (German states, 1801–1868) discovered magnetic deflection of electrons in a vacuum tube in 1857. See Fig. 6.38.

By harnessing Plücker's discovery, Karl Ferdinand Braun (German, 1850–1918) invented and demonstrated cathode ray tubes and oscilloscopes in 1897 (Fig. 6.38). Oscilloscopes are essentially television sets that visually display sine waves corresponding to electrical input signals; they have been used in various forms ever since as important diagnostic and readout instruments for electronic systems. In much of the world, cathode ray tube screens are still called Braun tubes. Braun also invented semiconductor diodes in 1874 (p. 1045) and won the Nobel Prize in Physics in 1909 for his radio-related research (p. 978).

Paul Nipkow (German, 1860–1940, Fig. 6.38) worked on an electromechanical television system that used a "Nipkow disk" to guide its scanning pattern. Nipkow's work greatly facilitated and inspired research by many other scientists after that.

In 1909, Ernst Ruhmer (German, 1878–1913) demonstrated a proof-of-concept 5x5 pixel CCD-like semiconductor television camera and a 5x5 pixel flat-panel television display (Fig. 6.39). He sought funding to build television cameras and displays with 100x100 pixels, but unfortunately he fell ill and died.

Some other early pioneers of television included August Karolus (German, 1893–1972), Kálmán Tihanyi (Hungarian, 1897–1947), Max Knoll (German, 1897–1969, one of the inventors of electron microscopes—see p. 1290), and Erhard Kietz (German, 1909–1982), as shown in Fig. 6.40.

Siegmund Loewe (German, 1885–1962) and Manfred von Ardenne (German, 1907–1997) developed a complete television transmitter and receiver system in 1931, and then an improved and larger television receiver in 1936 (Fig. 6.41). Figure 6.42 also shows a competing Telefunken commercial television receiver from 1933.

Emil Mechau (German, 1882–1945), Walter Heimann (German, 1908–1981), and Werner Flechsig (German, 1900–1981) developed the long-range zoom television cameras that were used to broadcast the 1936 Berlin Olympics (Fig. 6.43).

Fritz Schröter (German, 1886–1973) at Telefunken developed interlaced television scanning and rectangular picture tubes, such as the 1937 television receiver shown in Fig. 6.44; he also did seminal work on pulse code modulation and analog-to-digital converters [FIAT 865]. Fritz Fischer (Swiss, 1898–1947) and Edgar Gretener (Swiss 1902–1958, also important in cryptography) developed television projectors. Friedrich Gladenbeck (German, 1899–1987, also important in robotics, p. 1209) developed high-frequency radio, remote control, and television systems.

Figure 6.45 shows a Telefunken television camera and Einheitsempfänger E1 home receiver, both from 1939. Late 1930s German television broadcasts featured a wide variety of regular news and entertainment shows with 441 horizontal lines of resolution for the height of the picture and 50 interlaced frames per second (25 full frames per second), fully comparable in both quality and content to American television of two decades later [Kloft 2000].

German-speaking scientists miniaturized television systems for use in smart bombs and missiles, decades before that technology became popularized in the first U.S.-Iraq war (pp. 1842–1844, 5412–5417). The same technology was also employed in battlefield robotics (pp. 1209–1210). Figures 6.46–6.48 show a shoebox-sized Fernseh television receiver/picture tube and shoebox-sized Tonne television camera/transmitter that were first operational in 1942.

CIOS XXXII-125, *German Guided Missile Research*, pp. 139–143, described the miniaturized television systems and some of their applications (see pp. 5412–5417):

> 3. Television System for Guided Missiles.
>
> This consists of two units (camera and transmitter) in the missile, and a further two circuits (receiver and indicator) in the controlling aircraft.
>
> All units measure 7" x 7" x 14½". Only the camera and indicator were designed by Fernseh, the radio link being designed by another firm.
>
> In the early models a 441 line interlaced picture was used, the picture frequency being 25 per second (frame frequency 50 per second). [...]
>
> The picture quality obtained would appear to be excellent. Some photographs have been obtained of the picture given by the 441 line interlaced equipment. These pictures were

> taken using the whole equipment, including the radio link, but a large, good quality receiving tube was used. The photographs indicate that the definition was about as good as can be obtained with a 441 line system. [...]
>
> The D.F.S. have been concerned with the testing and installation of the Fernseh television in the Hs 293. [...]
>
> On one test a range of 263 kms. was obtained with the controlling aircraft at a height of 4,000 metres and the bomb at a height of 1,000 metres. [...]
>
> It is understood that the Fernseh television camera using the infra-red tube was also used in the robot tank. [...]
>
> An interesting television camera of very compact design is being developed for Wasserfall. [...]

In "Nazis Had Television Eye to Guide Missile's Path," the *New York Times* reported [NYT 1949-05-22]:

> DAYTON, Ohio, May 21—German scientists during World War II developed a television device similar to the human eye for controlling guided missiles or aircraft but never put it to use, the Air Materiel Command at Wright Field disclosed today.
>
> The device was built into missiles such as bombs and guided them toward a pre-set target without outside help, it was said. It used a movable mirror which reflected the target to a television tube. This tube transmitted electrical impulses to the missile's steering device, keeping the missile constantly pointed at the target.
>
> The pilot aligned his target in the television picture in his sighting mechanism, switched on the bomb's steering device and released the bomb. The missile then was on its own.
>
> The entire device was no bigger than eight inches in diameter and weighed only four pounds. Some were as small as five inches in diameter.

In addition to such military applications, handheld compact video cameras based on this technology were used for many decades after the war.

These wartime video cameras and television receivers could also achieve remarkable resolution. Some systems transmitted images up to 1029 horizontal lines in height at 25 frames per second [Faensen 2001, p. 90], comparable to modern high-definition television (HDTV, 1080 lines) and far greater than the 480-line standard resolution that was used for U.S. commercial television broadcasts until the early 2000s.

Walter Bruch (German, 1908–1990) operated television cameras at the 1936 Berlin Olympics and then developed the color PAL television system after the war. See Fig. 6.49.

Peter Carl Goldmark (Hungarian, 1906–1977) developed magnetic video recording (the Electronic Video Recording system, 1967), as well as LP records and a color television system in the United States (Fig. 6.49).

Robert Adler (Austrian, 1913–2007, Fig. 6.50), a physicist from Vienna, joined Zenith Electronics in the United States in 1941 and patented a huge number of television-related inventions, including remote controls (using ultrasonic or optical signals), subscription television channels (using scrambled and descrambled signals), and color television systems.

German-speaking scientists also invented both light-emitting diodes (LEDs, pp. 1104 and 2888) and liquid crystals (p. 506), which are the basis of modern video screens.

6.3.10 Video Telephone System

Georg Oskar Schubert (German, 1900–1955), working with other engineers at Fernseh and the Reichspost, combined the new television technologies with the already advanced German telephone system, and offered the first public video telephone system beginning in 1936 (Fig. 6.51). The system featured two-way video and audio, a broadband coaxial cable network, and service for customers in cities such as Berlin, Hamburg, Leipzig, Munich, Nuremberg, etc.[7]

During the war, this system was greatly expanded (for example, even including service to underground installations in remote parts of the Reich—see p. 4508) but used only for government business.

Although this system ceased operation in 1945, it was many decades ahead of its time, and the direct forerunner of now-common video teleconferencing calls.

Nearly three decades after the introduction of the German public video telephone system, and after a massive postwar transfer of technologies from Germany (Section B.5), AT&T Bell Laboratories announced it had just then "invented" the "first" public video telephone system [*Look*, 11 August 1964, p. 9]. See Fig. 6.52.

6.3.11 Scanners, Facsimile (Fax) Machines, and Printers

High-speed electronic scanners and facsimile or fax machines were developed in the German-speaking world and transferred to other countries after World War II [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards]. See Figs. 6.53–6.54. Many people were involved in their development, but special mention should go to Arthur Korn (German, 1870–1945) for doing some of the earliest work on this topic, and to Rudolf Hell (German, 1901–2002) for creating fully functional scanners, fax machines, and printers. See also FIAT 908, *The Siemens and Halske Teleprinter, T-Typ 68.*

Georg Schubert (1900–1955)

Created and offered the first public video telephone system (Fernseh/Reichspost, 1936–):

- **Two-way video and audio**
- **Broadband coaxial cable network**
- **Serving customers in Berlin, Hamburg, Leipzig, Munich, Nuremberg, etc.**
- **Expanded during the war but used only for government business 1940–1945**

Video telephone system

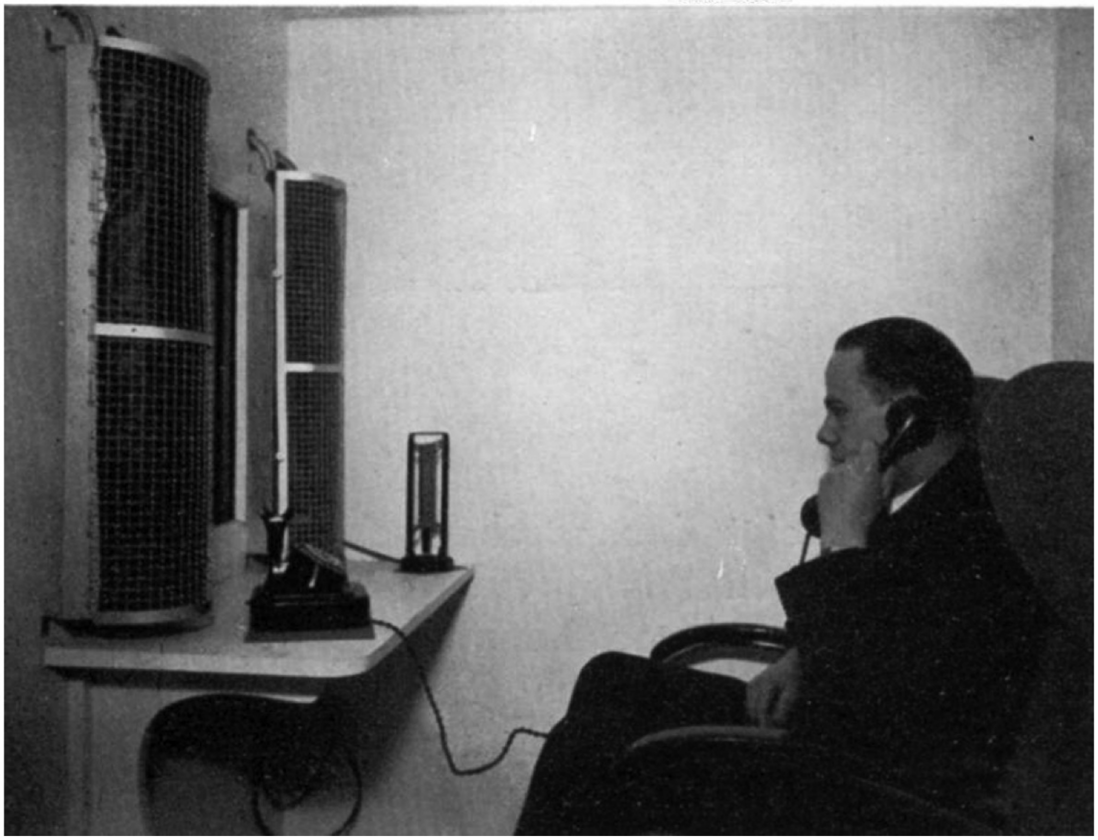

Figure 6.51: Georg Schubert, working with other engineers at Fernseh and the Reichspost, created and offered the first public video telephone system in 1936.

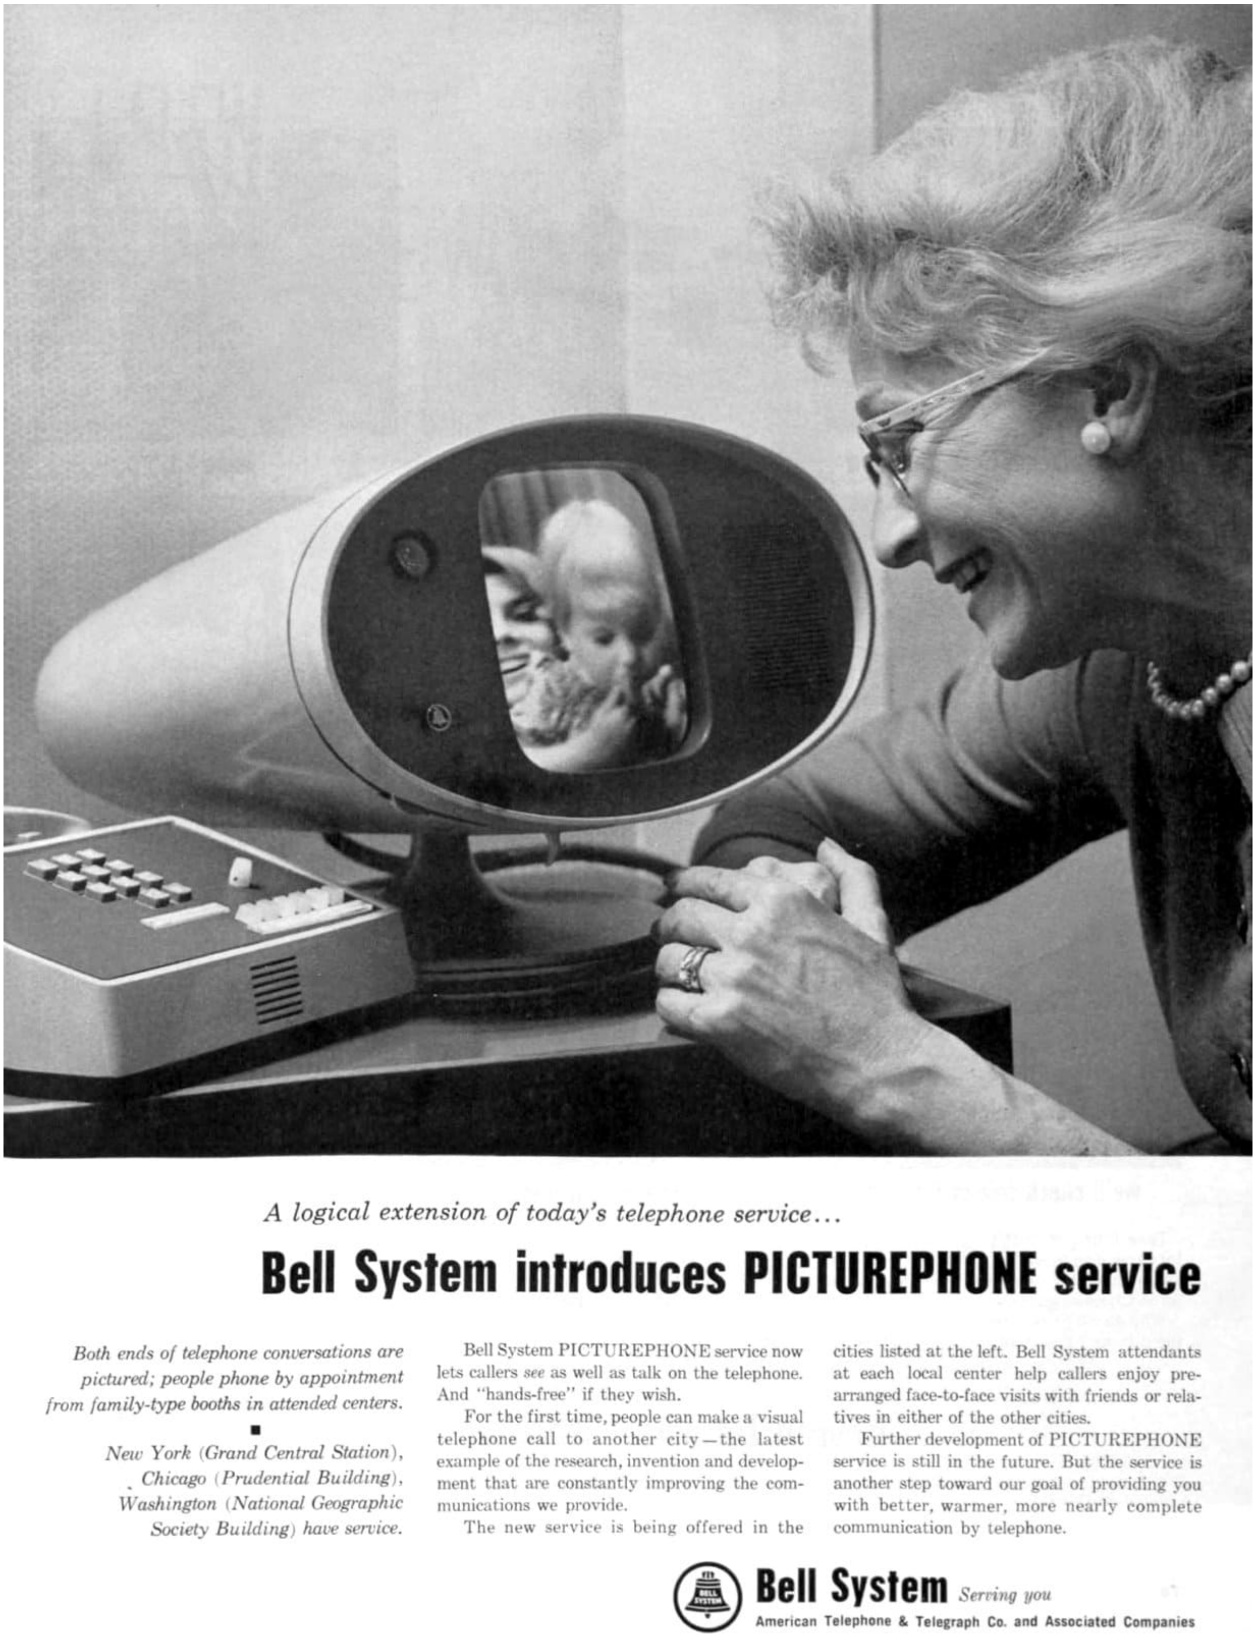

A logical extension of today's telephone service…

Bell System introduces PICTUREPHONE service

Both ends of telephone conversations are pictured; people phone by appointment from family-type booths in attended centers.

■

New York (Grand Central Station), Chicago (Prudential Building), Washington (National Geographic Society Building) have service.

Bell System PICTUREPHONE service now lets callers *see* as well as talk on the telephone. And "hands-free" if they wish.

For the first time, people can make a visual telephone call to another city—the latest example of the research, invention and development that are constantly improving the communications we provide.

The new service is being offered in the cities listed at the left. Bell System attendants at each local center help callers enjoy prearranged face-to-face visits with friends or relatives in either of the other cities.

Further development of PICTUREPHONE service is still in the future. But the service is another step toward our goal of providing you with better, warmer, more nearly complete communication by telephone.

Bell System *Serving you*

American Telephone & Telegraph Co. and Associated Companies

Figure 6.52: Nearly three decades later, and after a massive postwar transfer of technologies from Germany (Section B.5), AT&T Bell Laboratories announced it had just then "invented" the "first" public video telephone system [*Look*, 11 August 1964, p. 9].

XII

HIGH SPEED FACSIMILE

The discovery of German developments accomplished in the field of Facsimile Communications Systems as a result of wartime research which they conducted for the purpose of meeting high speed communications requirements between airplanes and ground stations will provide American communication companies with information which will be of inestimable value in their efforts to increase the speed of transmission of such communications.

The Germans were seeking a method for transmitting images of messages or pictures very rapidly and in short bursts, as a further means of secret communication. The speed of transmission which the Germans developed was not only considerably faster than that developed thus far domestically but also could be varied. The combination of these factors resulted in the elimination of the possibility of interception of such communications.

By the use of the highest speed developed by the Germans, facsimile communications can be transmitted approximately twenty times faster than that used thus far by domestic communications carriers. Recording of the messages at the receiving station was done photographically and the resolution was of such high quality that only an expert could distinguish between the copy and the original. Such resolution is unobtainable by the American method which employs a dry reproduction process involving the use of a carbon impregnated paper at the receiving station.

All indications are that the exploitation of this development by American communications companies will result in reducing such domestic communication transmission costs if for no other reason than the fact that the circuit use time required for the transmission of such messages can be appreciably reduced.

Information concerning this German development will be made available through the Office of Technical Services of the Department of Commerce.

Figure 6.54: High-speed electronic scanners and facsimile or fax machines were developed in the German-speaking world and transferred to other countries after World War II [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards].

6.3.12 Photocopiers

Photocopier technology was developed in the German-speaking world and then transferred to other countries during and after the Third Reich. Early forms of the technology used chemically coated, light-sensitive paper. There is some evidence that the modern form of photocopiers, using powdered ink electrostatically attracted to uncoated paper, may have also been developed in wartime Germany, although much more archival research is needed on this topic.

Allied investigators wrote many reports on German photocopier technology after the war. For example, BIOS 1255, *Research in the German Printing Industry*, p. 17, stated:

> The Suitability of Mercury Vapour Lamps for Exposing
> Pigment Paper for Photogravure: by J. Albrecht and O. Watter.
>
> Comparisons were made on the copying effect of carbon arcs, high-pressure mercury vapour lamps and fluorescent lamps.
>
> At even-distance carbon arcs are superior in using the least energy for equal copying effect but in practice the conditions are varied by the fact that the carbon arc does have a point source combined with high heat-output whereas fluorescent tubes distribute the light emission over a fairly large area with consequent lower heat generation per unit area and permit exposure at much closer distances at the time, giving better light-distribution.
>
> High-pressure mercury vapour lamps are not quite as suited as fluorescent tubes.
>
> Description of a practical arrangement of fluorescent tubes for exposing pigment papers is given.

Among other examples of Allied reports on German photocopier technology, see:

6.3.13 Optical Discs and Digital File Formats

In 1935, Edwin Welte (German, 1876–1958) created a system for recording and playing back music from optical discs, as shown in Fig. 6.55. He patented and produced the system, and continued to improve it through World War II. Much of Welte's work was destroyed in Allied bombing near the end of the war, yet his innovations appear to have exerted direct or indirect influence on postwar work.

The development of lasers (which also originated in the German-speaking world—see Sections 6.4 and C.3) made it much more practical to record and read data on high-density optical discs. The most important postwar laboratory for developing laser optical discs was the Philips Eindhoven research center, which had been closely tied to the rest of the predominantly German-speaking research world from the late nineteenth century through World War II, including work on electronics, communications, and directed energy beams.[8] Various types of laser optical discs (LaserDiscs, compact discs or CDs, digital video discs or DVDs, etc.) were produced from 1969 onward at Philips Eindhoven by Gijs Bouwhuis (Dutch, 19??–), Piet Kramer (Dutch, 19??–), Klaas Compaan (Dutch, 19??–), Kees Schouhamer Immink (Dutch, 1946–), Lou Ottens (Dutch, 1926–), and Joop Sinjou (Dutch, 19??–). See Fig. 6.56. Laser optical disc technology was rapidly adopted by Japan, the United States, and other countries.

Beginning in 1970, Dieter Seitzer (German, 1933–) at the University of Erlangen pioneered methods to compress digital files without a noticeable loss of signal detail. Based on those methods, the now-ubiquitous MP3 digital audio file format was developed and perfected at the Fraunhofer Society by Seitzer's students and associates, including Karlheinz Brandenburg (German, 1954–), Ernst Eberlein (German, 19??–), Heinz Gerhäuser (German, 1946–), Bernhard Grill (German, 1961–), Jürgen Herre (German, 19??–), and Harald Popp (German, 1956–). See Fig. 6.57.

6.4 Lasers, Holography, and Laser Spectroscopy

Creators from the greater German-speaking world played key roles in the development of lasers (Section 6.4.1), holography (Section 6.4.2), and laser spectroscopy (Section 6.4.3).

6.4.1 Lasers

A laser (Light Amplification by Stimulated Emission of Radiation) produces light that all has the same wavelength and the same phase, which enables all of the optical power to be concentrated into just one wavelength or color instead of a broader spectrum, and also allows the beam to remain much more tightly focused than a normal beam of light can. (Because the laser light all has the same wavelength and phase unlike a normal light beam, constructive interference with itself keeps it on course, and destructive interference with itself prevents it from veering off course.) According to official histories, the idea of a laser was not proposed until the late 1950s by Charles Townes, Arthur Schawlow, and Gordon Gould, and the first laser was not built until 1960 by Theodore Maiman, all in the United States.[9]

In fact, most of the discoveries and innovations that led to lasers were made decades earlier by German-speaking scientists. Their discoveries prompted the far more publicly visible U.S. work in this field in the late 1950s and early 1960s.

As shown on pp. 1025 and 3102–3104, Albert Einstein (German, 1879–1955) first proposed the idea of stimulated light emission from atoms (amplification of the number of photons of light from atoms) in 1916.

During the period 1919–1926, Christian Füchtbauer (German, 1877–1959), James Franck (German, 1882–1964), Max Born (German, 1882–1970), Walther Bothe (German, 1891–1957), and Hendrik Kramers (Dutch, 1894–1952) separately wrote several journal articles further developing the theory of stimulated light emission from atoms. See pp. 1026 and 3105–3115.

Putting those theories into experimental practice, Rudolf Ladenburg (1882–1952), Hans Kopfermann (1895–1963), and other members of the Ladenburg group at the Kaiser Wilhelm Institut für Physikalische und Elektrochemie investigated and demonstrated stimulated photon emission from atoms of electrically excited gases during the period 1921–1931. See pp. 1027 and 3115–3127. Because Ladenburg was Jewish and faced rising antisemitism in Germany, he had to discontinue his experiments there and move to the United States. Unfortunately, the U.S. research system at the time had little interest in his work on stimulated photon emission, so his revolutionary progress toward lasers ended.

In 1934, Franz Weidert and Hans Löffler invented neodymium-doped glass with unusual spectral properties that made it suitable for a variety of optical applications, eventually including neodymium glass lasers. See pp. 3128–3132.

---

[9] See for example: Bertolotti 2015; Bromberg 1991; Hecht 2010; Taylor 2000; Townes 1999.

Ladenburg's research was carried further by Wilhelm von Meyeren (German, 1905–1983). In a 20 February 1945 report to Walther Gerlach, von Meyeren described his 1944 experiments with laser-like monochromatic stimulated light emission from electron population inversions in argon, cesium, or rubidium gases (pp. 1028 and 3137–3156). Von Meyeren appeared to be on the verge of creating an argon laser or other gas laser (or perhaps he succeeded, if he conducted further experiments not mentioned in this one surviving document). However, after the war ended in 1945, von Meyeren's Prague laboratory was ransacked, and von Meyeren was imprisoned for a while and eventually sent empty-handed to West Germany. His hardware and files may well have contributed to the later development of lasers in the Soviet Union.

There is also evidence that there was other major work on lasers in the German-speaking world during the war, and possibly even demonstrations of fully functional prototype lasers (pp. 3157–3179).

For more information on this early developmental work toward lasers, see Section C.3. Much more archival research is needed to investigate the complete history, full accomplishments, and ultimate influence of work in this field by German-speaking scientists.[10]

Semiconductor lasers or laser diodes were also created by German-speaking scientists. Laser diodes were designed and developed by John von Neumann (Hungarian, 1903–1957), Walter Heywang (German, 1923–2010), and Herbert Kroemer (German, 1928–). See pp. 1109–1111 and Section B.4.

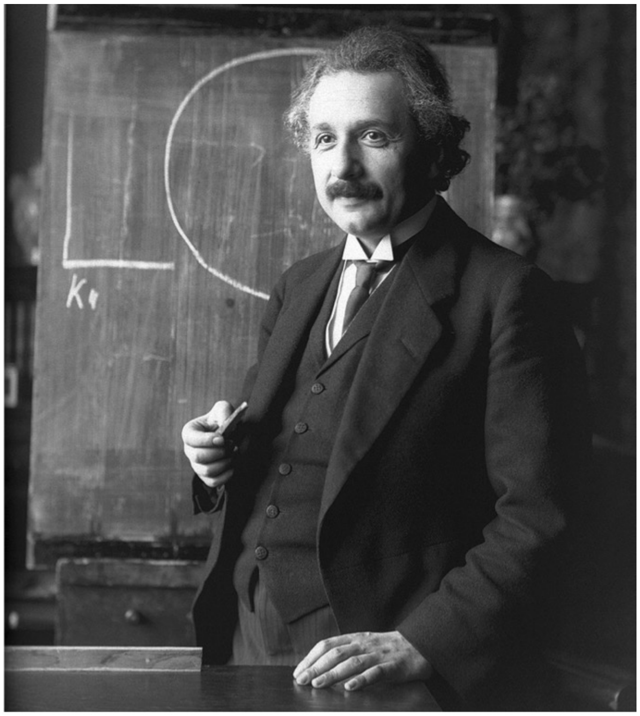
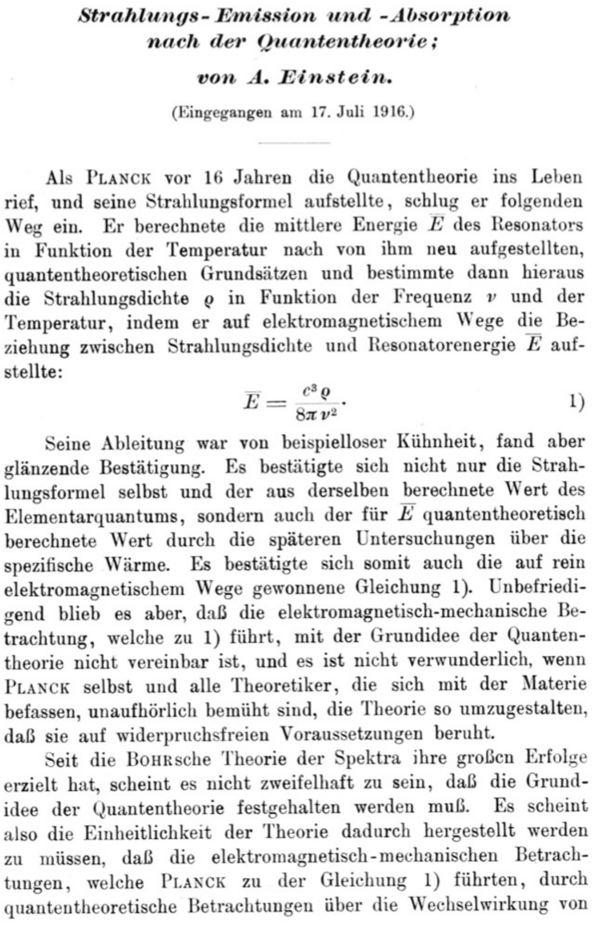
Lasers (Light Amplification by Stimulated Emission of Radiation)

Albert Einstein (1879–1955)

Theory predicting stimulated emission of photons (1916)





Strahlungs-Emission und -Absorption nach der Quantentheorie;

von A. Einstein.

(Eingegangen am 17. Juli 1916.)

Als Planck vor 16 Jahren die Quantentheorie ins Leben rief, und seine Strahlungsformel aufstellte, schlug er folgenden Weg ein. Er berechnete die mittlere Energie $\overline{E}$ des Resonators in Funktion der Temperatur nach von ihm neu aufgestellten, quantentheoretischen Grundsätzen und bestimmte dann hieraus die Strahlungsdichte ϱ in Funktion der Frequenz ν und der Temperatur, indem er auf elektromagnetischem Wege die Beziehung zwischen Strahlungsdichte und Resonatorenergie $\overline{E}$ aufstellte:

$$\overline{E} = \frac{c^3 \varrho}{8\pi \nu^2}. \qquad 1)$$

Seine Ableitung war von beispielloser Kühnheit, fand aber glänzende Bestätigung. Es bestätigte sich nicht nur die Strahlungsformel selbst und der aus derselben berechnete Wert des Elementarquantums, sondern auch der für $\overline{E}$ quantentheoretisch berechnete Wert durch die späteren Untersuchungen über die spezifische Wärme. Es bestätigte sich somit auch die auf rein elektromagnetischem Wege gewonnene Gleichung 1). Unbefriedigend blieb es aber, daß die elektromagnetisch-mechanische Betrachtung, welche zu 1) führt, mit der Grundidee der Quantentheorie nicht vereinbar ist, und es ist nicht verwunderlich, wenn Planck selbst und alle Theoretiker, die sich mit der Materie befassen, unaufhörlich bemüht sind, die Theorie so umzugestalten, daß sie auf widerpruchsfreien Voraussetzungen beruht.

Seit die Bohrsche Theorie der Spektra ihre großen Erfolge erzielt hat, scheint es nicht zweifelhaft zu sein, daß die Grundidee der Quantentheorie festgehalten werden muß. Es scheint also die Einheitlichkeit der Theorie dadurch hergestellt werden zu müssen, daß die elektromagnetisch-mechanischen Betrachtungen, welche Planck zu der Gleichung 1) führten, durch quantentheoretische Betrachtungen über die Wechselwirkung von

Zur Quantentheorie der Strahlung

von **A. Einstein.**

Die formale Ähnlichkeit der Kurve der chromatischen Verteilung der Temperaturstrahlung mit dem Maxwell'schen Geschwindigkeits-Verteilungsgesetz ist zu frappant, als daß sie lange hätte verborgen bleiben können. In der Tat wurde bereits W. Wien in der wichtigen theoretischen Arbeit, in welcher er sein Verschiebungsgesetz

$$\varrho = \nu^3 \, f\left(\frac{\nu}{T}\right) \qquad (1)$$

ableitete, durch diese Ähnlichkeit auf eine weitergehende Bestimmung der Strahlungsformel geführt. Er fand hiebei bekanntlich die Formel

$$\varrho = \alpha \nu^3 e^{-\frac{h\nu}{kT}} \qquad (2)$$

welche als Grenzgesetz für große Werte von $\frac{\nu}{T}$ auch heute als richtig anerkannt wird (Wien'sche Strahlungsformel). Heute wissen wir, daß keine Betrachtung, welche auf die klassische Mechanik und Elektrodynamik aufgebaut ist, eine brauchbare Strahlungsformel liefern kann, sondern daß die klassische Theorie notwendig auf die Reileigh'sche Formel

$$\varrho = \frac{k\alpha}{h} \nu^2 T \qquad (3)$$

führt. Als dann Planck in seiner grundlegenden Untersuchung seine Strahlungsformel

$$\varrho = \alpha \nu^3 \frac{1}{e^{\frac{h\nu}{kT}} - 1} \qquad (4)$$

auf die Voraussetzung von diskreten Energie-Elementen gegründet hatte, aus welcher sich in rascher Folge die Quantentheorie entwickelte, geriet jene Wien'sche Überlegung, welche zur Gleichung (2) geführt hatte, naturgemäß wieder in Vergessenheit.

Vor kurzem nun fand ich eine der ursprünglichen Wien'schen Betrachtung [1]) verwandte, auf die Grundvoraussetzung der Quanten-

Die räumliche Energieverteilung in der Hohlraumstrahlung.

Von **W. Bothe** in Charlottenburg.

(Eingegangen am 23. Oktober 1923.)

Einleitung. Die Hohlraumstrahlung ist ein statistisches Phänomen und muß als solches auch Schwankungserscheinungen aufweisen. Die theoretische Bedeutung der Energieschwankungen schätzt H. A. Lorentz[1]) so hoch ein, daß er von ihnen den Schlüssel für die ganze Strahlungstheorie erwartet. Dies ist folgendermaßen zu verstehen: Ist die mittlere Energie E eines Systems als Funktion der Temperatur T bekannt, so liefert die statistische Mechanik ohne weiteres einen Ausdruck für das mittlere Quadrat der Energieschwankungen Δ^2[2]):

$$\overline{\Delta^2} = kT^2 \frac{dE}{dT}, \tag{1}$$

wo k die Boltzmannsche Konstante ist. Auf die Plancksche Strahlungsformel

$$E = \frac{\alpha \nu^3}{e^{\frac{h\nu}{kT}} - 1} V \tag{2}$$

angewandt, lautet diese Gleichung:

$$\overline{\Delta^2} = h\nu E + \frac{h}{\alpha \nu^2} \frac{E^2}{V}, \tag{3}$$

wenn V das betrachtete Strahlungsvolumen ist; die übrigen Bezeichnungen sind die üblichen[3]). Jede Hypothese über die Struktur der Strahlung muß mit dieser Gleichung im Einklang sein. Nimmt man z. B. an, daß die Energie der Schwingungszahl ν in diskreten, voneinander unabhängigen Strahlungsquanten von der Größe $h\nu$ konzentriert ist, so findet man nach Analogie mit den Dichteschwankungen in einem idealen Gase:

$$\overline{\Delta^2} = h\nu E.$$

(Mitteilung aus dem Kaiser Wilhelm-Institut für physikalische und Elektrochemie.)

Untersuchungen über die anomale Dispersion angeregter Gase.

V. Teil*.

Negative Dispersion in angeregtem Neon**.

Von **H. Kopfermann** und **R. Ladenburg** in Berlin-Dahlem.

Mit 6 Abbildungen. (Eingegangen am 12. August 1930.)

Bei Steigerung der Stromdichte in der positiven Säule einer Neon-Entladung findet man zunächst ein Ansteigen der anomalen Dispersion an den rotgelben s-p-Linien, gemessen durch die Werte $\mathfrak{N}$, und zwar verhalten sich alle zum gleichen unteren s-Zustand gehörigen Linien in gleicher Weise — dies entspricht dem Ansteigen der Atomdichten im s-Zustand N_s. Vermehrt man aber die Stromdichte über $\sim 0{,}1$ Amp./qcm (bei 1 mm Neondruck), so nehmen die $\mathfrak{N}$-Werte wieder langsam ab, und zwar für die verschiedenen Linien $s_5 - p_{10}$, p_9, p_8 . . . bis p_2 in merklich verschiedener Weise (Fig. 4 und 5). Dies ist durch das allmähliche und verschieden starke Anwachsen der Atomdichten in den p-Zuständen, $N_{p_{10}}$, N_{p_9} ... zu deuten und durch die dadurch hervorgerufene „negative Dispersion" gemäß der Formel

$$\mathfrak{N}_{s_5 p_k} = N_{s_5} f_{s_5 p_k} \left(1 - \frac{N_{p_k}}{N_{s_5}} \frac{g_{s_5}}{g_{p_k}}\right).$$

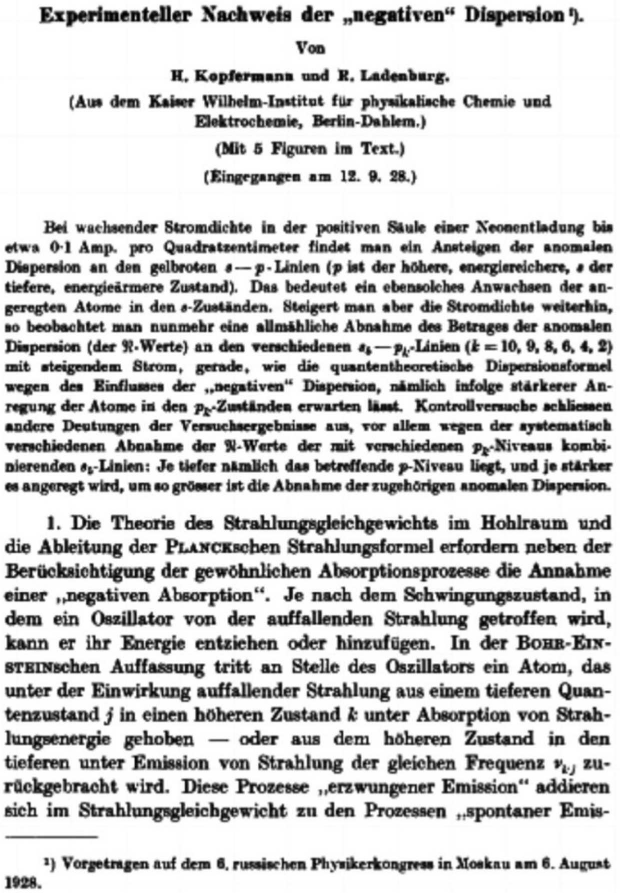
Diese Deutung wird durch Untersuchung der „Umkehr" der Neonlinien bestätigt, die ein ähnliches Anwachsen des Verhältnisses $V = N_{p_k}/N_{s_5} \cdot g_{s_5}/g_{p_k}$ zeigt. Aus den Messungen läßt sich unter gewissen theoretisch näher begründeten Annahmen über die Stromabhängigkeit der Atomdichte im s_5-Zustand das Verhältnis V und der Anstieg der N_{p_k}-Werte mit dem Strom berechnen (Fig. 6). Bei dem größten bisher erreichten Strom von 700 mA in einem 0,8 cm weiten Rohr nähern sich die N_p-Werte einem „Sättigungswert", es scheint sich ein statistisches Gleichgewicht zwischen den Atomdichten in den verschiedenen Zuständen und den anregenden und vernichtenden Elektronen auszubilden. Definiert man die zu den s- und p-Zuständen gehörige spezifische Temperatur Θ durch die Formel

$$\ln V_{ps} = -\frac{E_p - E_s}{k\ \Theta_{sp}} = -\frac{h\,c}{k\ \lambda_{sp}} \frac{1}{\Theta_{sp}},$$

---

* Teil I, II, III und IV der U. a. D. siehe ZS. f. Phys. **48**, 15, 26, 51 u. 192, 1928. Sie werden hier als U. a. D. I . . . IV zitiert.

** Ein Teil der in vorliegender Mitteilung dargestellten Versuche und Überlegungen wurde bereits in dem Haber-Band der ZS. f. phys. Chem. (A) 375, 1928 veröffentlicht.



Experimenteller Nachweis der „negativen" Dispersion[1].

Von

H. Kopfermann und R. Ladenburg.

(Aus dem Kaiser Wilhelm-Institut für physikalische Chemie und Elektrochemie, Berlin-Dahlem.)

(Mit 5 Figuren im Text.)

(Eingegangen am 12. 9. 28.)

Bei wachsender Stromdichte in der positiven Säule einer Neonentladung bis etwa 0·1 Amp. pro Quadratzentimeter findet man ein Ansteigen der anomalen Dispersion an den gelbroten $s - p$-Linien (p ist der höhere, energiereichere, s der tiefere, energieärmere Zustand). Das bedeutet ein ebensolches Anwachsen der angeregten Atome in den s-Zuständen. Steigert man aber die Stromdichte weiterhin, so beobachtet man nunmehr eine allmähliche Abnahme des Betrages der anomalen Dispersion (der $\mathfrak{N}$-Werte) an den verschiedenen $s_5 - p_k$-Linien ($k = 10, 9, 8, 6, 4, 2$) mit steigendem Strom, gerade, wie die quantentheoretische Dispersionsformel wegen des Einflusses der „negativen" Dispersion, nämlich infolge stärkerer Anregung der Atome in den p_k-Zuständen erwarten lässt. Kontrollversuche schliessen andere Deutungen der Versuchsergebnisse aus, vor allem wegen der systematisch verschiedenen Abnahme der $\mathfrak{N}$-Werte der mit verschiedenen p_k-Niveaus kombinierenden s_5-Linien: Je tiefer nämlich das betreffende p-Niveau liegt, und je stärker es angeregt wird, um so grösser ist die Abnahme der zugehörigen anomalen Dispersion.

1. Die Theorie des Strahlungsgleichgewichts im Hohlraum und die Ableitung der PLANCKschen Strahlungsformel erfordern neben der Berücksichtigung der gewöhnlichen Absorptionsprozesse die Annahme einer „negativen Absorption". Je nach dem Schwingungszustand, in dem ein Oszillator von der auffallenden Strahlung getroffen wird, kann er ihr Energie entziehen oder hinzufügen. In der BOHR-EINSTEINschen Auffassung tritt an Stelle des Oszillators ein Atom, das unter der Einwirkung auffallender Strahlung aus einem tieferen Quantenzustand j in einen höheren Zustand k unter Absorption von Strahlungsenergie gehoben — oder aus dem höheren Zustand in den tieferen unter Emission von Strahlung der gleichen Frequenz ν_{kj} zurückgebracht wird. Diese Prozesse „erzwungener Emission" addieren sich im Strahlungsgleichgewicht zu den Prozessen „spontaner Emis-

12/3

Problemstellung. Es sollen die Atome eines Gases oder Dampfes vom Grundzustand aus in den ersten angeregten /nicht metastabilen/ Zustand gehoben werden, derart, dass dabei höher angeregte Zustände möglichst nicht oder doch nur in verschwindend geringer Zahl vorkommen. Das Gas bezw. der Dampf kann dann lediglich die Resonanzlinie des betr. Atoms emittieren, stellt dann also eine praktisch monochromatische Lichtquelle dar.

Bei der Verwendung von Rubidium- oder Cäsiumdampf wäre dann lediglich Strahlung der Wellenlängen 7984 und 78oo A.E./Rb/ bezw. 8944 und 8521 A.E./Cs/ zu erwarten, also je zwei diskrete im nahen ultraroten Spektralgebiet gelegene Strahlungsfrequenzen. Dass für jedes Atom zwei Frequenzen auftreten müssen, rührt von der Dublettaufspaltung der P-Terme her.

Um eine solche Lichtquelle von hinreichend grosser Strahlungsintensität zu erhalten, muss die Zahl der im ersten angeregten Zustand befindlichen Atome möglichst gross gemacht werden. Es kommt deshalb nur Anregung durch Elektronenstoss in Frage unter Verwendung einer ergiebigen Glühkathode als Elektronenquelle.

Ferner liegt es nahe, ein Gas bezw. einen Dampf von höher Dichte zu benutzen, um eine grosse Zahl angeregter Zustände zu erhalten.

Die Verwendung eines hohen Gas- bezw. Dampfdruckes erweist sich aber aus folgenden Gründen als ungeeignet. Durch unvermeidliche Mehrfachstösse werden auch stets höhere Terme der Atome angeregt, und zwar umso mehr, je höher Gasdruck und Stromdichte sind. Ferner steigt ~~steigt~~ mit zunehmender Gasdichte die Wahrscheinlichkeit für das Eintreten von Stössen 2.Art. Diese verursachen wiederum grosse Geschwindigkeiten der stossenden Elektronen und damit eine Vergrösserung der Anregungswahrscheinlichkeit für höhere Atomzustände.-

In früheren Untersuchungen hat Verf. gezeigt, dass auch in Gasen von sehr kleiner Dichte durch Elektronen kleiner Stromdichte eine sehr starke Anregung möglich ist. Die mittlere freie Weglänge der Elektronen nimmt zwar bei abnehmendem Gasdruck zu und erreicht bereits bei Drucken von der Grössenordnung o,ol Torr die linearen Dimensionen der gebräuchlichen Entladungsgefässe, also einige Zentimeter. Zwingt man aber durch Anlegen eines äusseren Magnetfeldes die Elektronen auf krummlinige Bahnen /Cykloiden, Kegelschraubenbahnen, u.dgl./, so lässt sich selbst bei sehr niederen Gasdrucken in normalen Entladungsgefässen die Zahl der anregenden Zusammenstösse zwischen Elektronen und Atomen ungeheuer steigern und ein intensives Gasleuchten erreichen. Gleichzeitig ist bei einer solchen Anordnung der weitere Vorteil verbunden, dass bei dem niederen Druck eine strahlungslose Rückkehr der angeregten Atome durch Zusammenstösse mit ~~neutralen~~ ~~Ato~~ nichtangeregten Atomen nur selten vorkommt. Untersuchungen dieser Art sind früher mit Stosselektronen grosser Geschwindigkeit /etwa 2.1o^5 e-Volt/ durchgeführt worden. Bei diesen Versuchsbedingungen werden auch hochangeregte Atomzustände und auch angeregte Zustände des Atomions in grosser Zahl geschaffen.

Zur möglichst alleinigen Anregung der Resonanzlinie des Atoms muss daher versucht werden, bei niederem Gasdruck mit langsamen Elektronen anzuregen. Für die Fälle des Rubidium- und Cäsiumatoms dürfen die Elektronengeschwindigkeiten dabei nur etwa 2 e-Volt

2

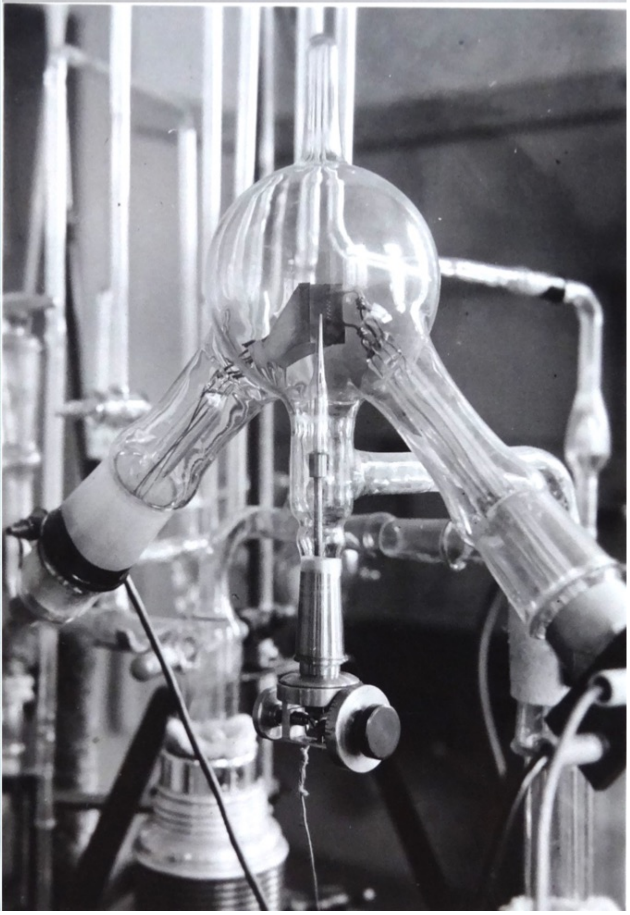

Figure 6.61: In a 20 February 1945 report to Walther Gerlach, Wilhelm von Meyeren described his 1944 experiments with laser-like monochromatic stimulated light emission from electron population inversions in argon, cesium, or rubidium gases.

6.4.2 Holography

Ludwig Mach (Austrian, 1868–1951) and Ludwig Zehnder (Swiss, 1854–1949) developed the Mach-Zehnder interferometer during the period 1891–1892. A Mach-Zehnder interferometer splits a collimated and preferably monochromatic beam of light into two beams, passes one beam through a transparent object (or reflected off a non-transparent object), then recombines the beams, which are projected onto a screen. Phase changes to the light waves caused by the object create constructive and destructive interference and thus visible patterns that can provide useful information about the object. See Fig. 6.62.

Ludwig Mach was the son of Ernst Mach (Austrian, 1838–1916). Ludwig and Ernst Mach used similar principles to visualize shock waves around bullets traveling faster than the speed of sound through air (p. 1657).

The Mach-Zehnder interferometric approach was later applied to microscopes, resulting in phase contrast microscopy (p. 1274).

In 1947, Dennis Gabor (Hungarian but educated and worked in Germany, 1900–1979) invented holography by applying Mach-Zehnder interferometry to photography (Fig. 6.63). Essentially, a holographic recording system is a Mach-Zehnder interferometer used as a camera, with photographic film placed at the final point to record the constructive and destructive interference produced when half of the light beam encounters an object and then the two halves of the beam are recombined. Such an image appears three-dimensional to human eyes, unlike regular photographs. (Though invented in 1947, holography later became a more powerful and more practical technique once lasers were readily available to be used as the light source.)

For introducing and developing holography, Gabor won the Nobel Prize in Physics in 1971. Professor Erik Ingelstam of the Royal Academy of Sciences discussed the far-reaching applications of Gabor's methods [https://www.nobelprize.org/prizes/physics/1971/ceremony-speech/]:

> [...I]mportant information about the object is missing in a photographic image. This is a problem which has been a key one for Dennis Gabor during his work on information theory. Because the image reproduces only the effect of the intensity of the incident wave-field, not its nature. The other characteristic quantity of the waves, phase, is lost and thereby the three dimensional geometry. The phase depends upon from which direction the wave is coming and how far it has travelled from the object to be imaged.
>
> Gabor found the solution to the problem of how one can retain a wave-field with its phase on a photographic plate. A part of the wave-field, upon which the object has not had an effect, namely a reference wave, is allowed to fall on the plate together with the wave-field from the object. These two fields are superimposed upon one another, they interfere, and give the strongest illumination where they have the same phase, the weakest where they extinguish each other by having the opposite phase. Gabor called this plate a hologram, from the Greek holos, which means whole or complete, since the plate contains the whole information. This information is stored in the plate in a coded form. When the hologram is irradiated only with the reference wave, this wave is deflected in the hologram structure, and the original object's field is reconstructed.

The result is a three dimensional image.

Gabor originally thought of using the principle to make an electron microscope image in two steps: first to register an object's field with electron rays in a hologram, and then to reconstruct this with visible light to make a three dimensional image with high resolution. But suitable electron sources for this were not available, and also for other technical reasons the idea could not be tested. However, through successful experiments with light Gabor could show that the principle was correct. In three papers from 1948 to 1951 he attained an exact analysis of the method, and his equations, even today, contain all the necessary information. [...]

The fascinated observer's admiration when he experiences the three dimensional space effect in a holographic image is, however, an unsufficient acknowledgement for the inventor. More important are the scientific and technical uses to which his idea has led. The position of each object's point in space is determined to a fraction of a light wave-length, a few ten-thousandths of a millimetre, thanks to the phase in the wave-field. With this, the hologram has, in an unexpected way, enriched optical measurement techniques, and particularly interferometric measurements have been made possible on many objects. The shape of the object at different times can be stored in one and the same hologram, through illumination of it several times. When they are reconstructed simultaneously, the different wave-fields interfere with each other, and the image of the object is covered with interference lines, which directly, in light wavelengths, correspond to changes of shape between the exposures. These changes can also be, for example, vibrations in a membrane or a musical instrument.

Also, very rapid sequences of events, even in plasma physics, are amenable to analysis through hologram exposures at certain times with short light flashes from modern impulse lasers.

Gabor's original thought to use different waves for both steps within holography, has been taken up in many connections. It is especially attractive to use ultra sound waves for exposures, so that, in the second step, a sound field is reconstructed in the shape of an optical image. Despite significant difficulties there is work, with a certain amount of progress, being done in this area. Such a method should be of value for medical diagnosis, since the deflected sound field gives different information from that in X ray radiography.

Figure 6.63: Dennis Gabor invented holography (essentially using a Mach-Zehnder interferometer as a camera), Nicolaas Bloembergen used nonlinear optics to increase or decrease laser frequencies by multiples, and Theodor Wolfgang Hänsch developed more precise laser frequency standards.

6.4.3 Laser Spectroscopy

Nicolaas Bloembergen (Dutch, 1920–2017, Fig. 6.63) developed early magnetic resonance imaging (MRI) machines and invented methods of using nonlinear optics to convert laser beams of one frequency or wavelength into beams of other frequencies or wavelengths (for example by halving or by doubling the frequency). He won the Nobel Prize in Physics in 1981 for his laser work. Professor Ingvar Lindgren of the Royal Swedish Academy of Sciences described that research and its applications [https://www.nobelprize.org/prizes/physics/1981/ceremony-speech/]:

> Nicolaas Bloembergen has contributed to the development of laser spectroscopy in a different way. Laser light is sometimes so intense that, when it is shone on to matter, the response of the system could not be described by existing theories. Bloembergen and his collaborators have formulated a more general theory to describe these effects and founded a new field of science we now call non-linear optics. Several laser spectroscopy methods are based upon this phenomenon, particularly such methods where two or more beams of laser light are mixed in order to produce laser light of a different wave length. Such methods can be applied in many fields, for instance, for studying combustion processes. Furthermore, it has been possible in this way to generate laser light of shorter as well as longer wave lengths, which has extended the field of application for laser spectroscopy quite appreciably.

Theodor Wolfgang Hänsch (German, 1941–, Fig. 6.63) developed more precise laser frequency standards, for which he won the Nobel Prize in Physics in 2005 (along with John Hall). Professor Stig Stenholm, a member of the Royal Swedish Academy of Sciences, explained the importance of the innovation [https://www.nobelprize.org/prizes/physics/2005/ceremony-speech/]:

> John Hall and Theodor Hänsch have worked on ever-improved standard references for frequency measurements. In order to compare an unknown period of light with the reference, they have developed the frequency comb technique. This gives a sequence of exactly separated frequencies and a method to set this measuring rod against an unknown frequency. Thus one obtains an extremely accurate number for the unknown period. This allows spectroscopic measurements with extremely high precision. Today this technique is as exact as the methods developed for this purpose during earlier decades, but it promises many times improved accuracy.
>
> The history of physics shows that, when the accuracy of measurements is improved, new physics may be discovered and explored. The work honored today facilitates tests of our basic theories in physics. The character of time and space may be clarified, and the limitations of the laws of physics may be established.

6.5 Solid State Physics and Microelectronics

German-speaking creators made many of the revolutionary advances in solid state physics and microelectronics that have made the modern world possible, yet to date, the full extent of their contributions has not been widely understood and recognized.[11]

This section gives an overview of the critical roles played by creators from the German-speaking world with regard to:

6.5.1. Solid state physics

6.5.2. Semiconductor materials and devices

6.5.3. Transistors

6.5.4. Postwar transfer of microelectronics technologies

6.5.5. Capacitors

6.5.6. Printed circuits

6.5.7. Integrated circuits

6.5.8. Light emitting diodes and laser diodes

6.5.9. Superconductivity

6.5.10. Piezoelectricity

For more extensive documentation in these areas, see Appendix B.

6.5.1 Solid State Physics

Solid state physics, the basic science underlying microelectronics, describes the motions of negatively charged electrons and positively charged ions in crystal lattices. Figure 6.64 gives a simple visual explanation of some of the major aspects of solid state physics.

There is a great need for someone to write a comprehensive and scientifically detailed history of German-speaking contributions to the combined area of solid state physics and microelectronics. Such a history should include all of the creators, creations, and evidence listed in this section and in Appendix B, and draw upon further archival research to solve many of the remaining mysteries.

---

[11] For individual pieces of the history of this area, see the documents in Appendix B and also: Arns 1998; Bernstein 1984; Crawford 1991; Eckert and Schubert 1990; Eisler 1989; Gertner 2012; Gimbel 1990a; Handel 1999; Hicks 2012; Hilsch 1939; Hilsch and Pohl 1938; Hoddeson et al. 1992; Hoddeson and Daitch 2002; Medawar and Pyke 2000; Metzler 2020; Mertz 1946; Nagel 2006; Noll and Geselowitz 2011; Pierce 1975; Rhoads 2005; Riordan and Hoddeson 1997; Sarkar et al. 2006; Saxena 2009; Sullivan 1949; Sze 1991; Teichmann 1988; Warnow-Blewett and Teichmann 1992.

As shown in upper part of Fig. 6.64, electrons belong to different energy levels, or energy bands, depending on whether the electrons behave like waves with peaks between the ions (higher energy, conduction band) or like waves with peaks at the ions (lower energy, valence band). In the illustration, electrons moving through a simple one-dimensional lattice of positively charged ions behave as standing waves with a wave function $\Psi(x)$. The magnitude of the wave function squared, $|\Psi(x)|^2$, represents the probability that the electrons will be at a given location, so electrons will usually be found near the antinodes (maxima) of the standing waves. If the electron wave function has antinodes between the ion locations as in the upper graph, the negatively charged electrons will tend to be found far away from positively charged ions, so they will have higher energies. If the electron wave function has antinodes near the ion locations, the negatively charged electrons will tend to be found very close to the positively charged ions, so they will have lower energies. Thus there are different possible levels or bands of energies for the electrons, and they are separated by an energy band gap.

The lower part of Fig. 6.64 is a schematic illustration of the occupation of electron energy bands in metals, insulators, semiconductors, and semimetals:

- In metals, an energy band is 10–90% filled. That provides plenty of electrons in the band, but it leaves them lots of nearby vacant energy states they can move to in order to run around and conduct electricity.
- In electrical insulators, each band is either completely full or completely empty. Completely full bands do not provide their electrons with nearby vacant states they can move to in order to conduct electricity, and completely empty bands do not have any electrons to conduct electricity. The band gap between the highest filled band and the lowest empty band is large enough that essentially no electrons from the filled band can jump up to the empty band and conduct electricity.
- Semiconductors are very similar to insulators, except that the energy band gap between the highest filled band (the valence band) and the lowest empty band (the conduction band) is much smaller. Because the band gap is smaller, a small but significant number of electrons can jump up to the conduction band and conduct electricity. These electrons leave behind vacant states in the valence band; the vacant states are called “holes” and act like positive charge-carrying particles.
- Just like semiconductors, semimetals also have a small but significant number of electrons in one band and a corresponding collection of holes in another. However, in semimetals, this effect is due to a negative energy band gap between two bands; an essentially full band overlaps in energy with an essentially empty band, causing some electrons to leave the full energy band and occupy lower energy states in the nearly empty band.

While the ions cannot move as freely as the electrons in a solid, they can vibrate in place, and those vibrations can carry energy. By considering the motions of both the electrons and the ions, solid state physics is able to explain the electrical, magnetic, optical, and thermal properties of solid materials.

Figure 6.64: Solid state physics, the basic science underlying microelectronics, describes the motions of negatively charged electrons and positively charged ions in crystal lattices. Electrons belong to different energy levels, or energy bands, depending on whether the electrons behave like waves with peaks between the ions (higher energy, conduction band) or with peaks at the ions (lower energy, valence band). Metals have a band partially full of electrons, with plenty of room for them to gain energy and run around. Electrical insulators have bands filled with electrons, and a large energy gap separating those from unfilled bands where they could run around. Semiconductors and semimetals have bands that can be more or less full, depending on the conditions.

In a crystalline solid, the ions are arranged in a three-dimensional periodic pattern or lattice, which has a large effect on the properties of the solid. For different solids with different crystal shapes, those three-dimensional lattice structures can be quite complex. Real crystals often have imperfections such as individual ions that have been knocked out of their correct locations within the lattice. Such lattice defects often absorb certain colors of visible light and are known even in the English-speaking physics community as “F centers” for the German word for color, Farbe.

Some creators who made major contributions to solid state physics are shown in Figs. 6.65–6.69.

Franz Ernst Neumann (German, 1798–1895) was one of the first scientists to make a detailed study of the optical behavior of crystals based on their composition and shapes.

Woldemar Voigt (German, 1850–1919) made contributions to several areas of physics and wrote the first textbook on solid state physics (*Lehrbuch der Kristallphysik*) in 1910.

Arthur Schoenflies (German, 1853–1928) applied advanced mathematical methods such as group theory to the analysis of crystal structures. “Schoenflies notation” is still widely utilized in crystallography and solid state physics.

Eugene Wigner (Hungarian, 1902–1995) greatly extended the group theory methods of Schoenflies with applications in solid state physics and particle physics. He won a Nobel Prize in Physics in 1963 for this work (p. 1535).

Hendrik Lorentz (Dutch, 1853–1928) used what were then the latest ideas about electromagnetic waves and electrons to create one of the first mathematical models for the electrical and optical properties of solids. He won the Nobel Prize in Physics in 1902 (p. 891).

Paul Drude (German, 1863–1906) also created a mathematical model for electrons in solids. Although the Drude model only considered classical mechanics and electromagnetism, it can be used to analyze and obtain the correct expressions for several important solid state phenomena.

Gustav Wiedemann (German, 1826–1899) and Rudolph Franz (German, 1826–1902) measured the thermal conductivity and the electrical conductivity of metals at different temperatures. They showed empirically that the ratio of the thermal and electrical conductivities increased in direct proportion to the temperature, which came to be called the Wiedemann-Franz law. While the Drude model could explain many properties of solids, it could not correctly explain the Wiedemann-Franz law.

Wolfgang Pauli (Austrian, 1900–1958) showed that electrons obey what is now called the Pauli exclusion rule; every electron in an atom, a solid, or other system is an individualist that refuses to do exactly the same thing as any other electron in that system. For this discovery, Pauli won the Nobel Prize in Physics in 1945 (p. 899).

Arnold Sommerfeld (German, 1868–1951) greatly improved the Drude model by using the Pauli exclusion principle to explain the behavior of electrons in metals. The resulting Sommerfeld or Drude-Sommerfeld model of free electrons yielded theoretical predictions that agreed with the experimental measurements of the Wiedemann-Franz law.

Max Born (German, 1882–1970) wrote an early textbook (*Dynamik der Kristallgitter*) on solid state physics in 1915, and contributed to the subject further as one of the pioneers of quantum physics in the 1920s. He won the Nobel Prize in Physics in 1954 (p. 896).

Felix Bloch (Swiss, 1905–1983) incorporated the wave-like behavior of electrons into models of solids, and the mathematical wave functions of electrons in solids became known as Bloch functions. Bloch won a Nobel Prize in Physics in 1952 (p. 1516).

Ralph Kronig (German, 1904–1995) extended Felix Bloch's calculations of the wave-like behavior of electrons in solids; the updated theory later became known as the Kronig-Penney model. Kronig was also one of the first physicists to propose electron spin. Kronig and Hendrik Kramers (Dutch, 1894–1952) independently developed the Kramers-Kronig relations for the optical and electronic properties of solids.

Gregory Wannier (Swiss, 1911–1983) further improved the calculations of the wave-like behavior of electrons in solids, resulting in the Wannier functions. With Hendrik Kramers, he also discovered the Kramers-Wannier duality for the magnetic properties of solids.

Wilhelm Lenz (German, 1888–1957) and Ernst Ising (German, 1900–1998) developed what became known as the Ising model to explain the magnetic properties of solids.

Walther Nernst (German, 1864–1941) made important contributions to the statistical physics and thermal properties of solids. He won the Nobel Prize in Chemistry in 1920 (p. 913).

Peter Debye (Dutch, 1884–1966) calculated the effects of vibrations of the ions in a crystal lattice on the thermal properties of the crystal. He won a Nobel Prize in Chemistry in 1936 (p. 914).

Erwin Madelung (German, 1881–1972) modeled the electrostatic effects of all the ions on an individual ion or on the electrons, resulting in what is now known as the Madelung constant.

Rudolf Peierls (German, 1907–1995) made many major discoveries in solid state physics, including the behavior of the positive "holes" left behind by negative electrons that have left atoms, the properties of phonons or vibrations of the ion lattice, and the shapes of repeating zones in momentum space corresponding to the shapes of repeated crystal shapes in regular space (a fundamentally important discovery that was incorrectly later attributed to Léon Brillouin).

Walther Kossel (German, 1888–1956) studied the structure, bonding, and growth of crystals. He was the son of Albrecht Kossel (p. 90).

Hans Bethe (German, 1906–2005) wrote his doctoral thesis on solid state physics and continued to make new discoveries in the field until after World War II. He won a Nobel Prize in Physics in 1967 (p. 1542).

Georg Joos (German, 1894–1959) gathered a wide variety of solid state physics theories and experiments and assimilated them into organized textbooks that taught several generations of physicists.

Während die Ausbreitung der elektromagnetischen Wirkungen in Raum und Zeit nach unserer Erfahrung durch die Maxwellschen Gleichungen ihre vollkommene Darstellung findet, steht die heutige theoretische Physik vor ernsten Schwierigkeiten, wo es sich um die Erzeugung oder Absorption von Licht, die Erzeugung lichtelektrischer Wirkungen oder sekundärer Strahlungen handelt. Diese Schwierigkeiten haben sogar (in der Lichtquantenvorstellung) zu einer völligen Abkehr von der ursprünglichen Maxwellschen Theorie und zu Konstruktionen geführt, die zwar die genannten Schwierig-

3. *Zur Theorie der spezifischen Wärmen; von P. Debye.*

Die Beobachtungen, welche im Laufe der letzten Zeit im Nernstschen Laboratorium über die Temperaturabhängigkeit der spezifischen Wärmen ausgeführt wurden, haben in überzeugendster Weise auch für materielle Körper die Unrichtigkeit des Satzes von der gleichmäßigen Energieverteilung dargetan. Bekanntlich hat Einstein[1]) zuerst auf die zu erwartenden Verhältnisse aufmerksam gemacht und unter Benutzung der von Planck[2]) für die Bedürfnisse der Strahlungstheorie entwickelten Quantenformel die spezifische Wärme als Funktion der Temperatur durch eine Formel dargestellt. Nun zeigen alle Messungen zwar einen Verlauf, welcher qualitativ der Einsteinschen Formel entspricht, quantitativ aber treten Abweichungen zwischen Theorie und Erfahrung zutage, welche um so erheblicher werden, je tiefer die Temperatur wird. Um diesen Übelstand abzuhelfen, haben Nernst und Lindemann die Einsteinsche Formel dahin abgeändert, daß sie neben der vorhandenen Schwingungszahl ν noch eine zweite Schwingungszahl $\nu/2$ in bekannter Weise einführen.[3]) Die Einführung dieser zweiten Schwingungszahl entspricht zwar durchaus dem praktischen Bedürfnis nach einer besseren Formel als die Einsteinsche, es ist indessen bis jetzt nicht gelungen, irgend einen stichhaltigen Grund für gerade diesen Wert $\nu/2$ ausfindig zu machen. Wir werden im folgenden sehen, daß ein tieferer Grund dafür auch nicht existiert. Wenn nun auch der Wert $\nu/2$ selbst keine weitere theoretische Begründung hat, so läßt sich doch andererseits die Notwendigkeit der Einführung mehrerer Schwingungszahlen plausibel machen, wie

11. *Zur Elektronentheorie der Metalle; von P. Drude.*

I. Teil.

Dass die Elektricitätsleitung der Metalle ihrem Wesen nach nicht allzu verschieden von der der Elektrolyte sei, insofern der elektrische Strom durch den Transport kleiner elektrischer Teilchen bewirkt wird, ist eine Anschauung, welche von W. Weber zuerst ausgesprochen und später von Giese[1]) weiter durchgeführt ist. Ich will diese elektrischen Teilchen im Anschluss an neuere Bezeichnungen *Elektronen*, oder (um einen bequemeren Ausdruck zu haben) *elektrische Kerne*, oder auch kurz *Kerne* nennen. Den Ausdruck Corpuskeln oder Ionen möchte ich vermeiden, da mit beiden Ausdrücken die Anschauung verbunden ist, dass die elektrischen Teilchen auch eine gewisse, wenn auch sehr kleine ponderable Masse mit sich führen. Ich glaube, es ist zweckmässiger, wenn der Ausdruck „Ionen“ für die Aggregate elektrischer Kerne und ponderabler Masse reservirt bleibt, welche wir in den Elektrolyten antreffen.

Ob ein Elektron eine sehr kleine ponderable Masse mit sich führt, oder nicht, lassen wir vorläufig unentschieden. Ich will nur gleich hier bemerken, dass es durchaus nicht nötig ist, einem Elektron ponderable Masse beizulegen, um ihm trotzdem eine gewisse kinetische Energie seiner Bewegung zuzuschreiben und eine Trägheit für Bewegungsänderungen, wie sie z. B. aus den Ablenkungen der Kathodenstrahlen im Magnetfeld und aus den optischen Eigenschaften der Metalle hervorgeht. Da jedes bewegte Elektron einen elektrischen Strom repräsentirt, welcher eine gewisse Anzahl magnetischer Kraftlinien im umgebenden Aether erzeugt, so müssen bei Antrieben, welche Richtung und Grösse der Geschwindigkeit des Elektrons zu ändern suchen, entgegenstehende Kräfte einsetzen, welche durch die Veränderung der vom bewegten Elektron hervor-

6.5.2 Semiconductor Materials and Devices

Harnessing solid state physics effects, especially those in semiconductors, led to the development of numerous microelectronic devices for various applications. Scientists from the greater German-speaking world took the lead in that area.

Karl Ferdinand Braun (German, 1850–1918) invented and demonstrated semiconductor diodes in 1874, using point contacts and crystals of metal sulfides for his first diodes (Fig. 6.70). Braun continued to experiment with and improve semiconductor diodes over the following years and ultimately harnessed them to develop radio systems. Braun also produced many other innovations in electronics, including oscilloscopes and phased array antennas. He won the Nobel Prize in Physics in 1909 for his radio-related research (p. 978).

In 1893, Julius Elster (German, 1854–1920) and Hans Geitel (German, 1855–1923) invented the semiconductor photoelectric cell, which could detect and measure the amount of light and produce a corresponding electrical output signal (Fig. 6.71). They continued to test photoelectric cells and devise applications for them for at least a decade, launching what became a large German industry. Elster and Geitel also made important discoveries on a wide variety of other topics in atmospheric physics, astronomy, nuclear physics, and other scientific areas.

In 1916, Jan Czochralski (Polish/German, 1885–1953) at the huge AEG electronics company developed a method for growing single, large, high-purity crystals of semiconductors or other materials (Fig. 6.72). The Czochralski method, as it became known, is now used worldwide to prepare semiconductor crystals, which are usually then sliced into wafers and chips.

Bernhard Gudden (German, 1892–1945) and Robert Pohl (German, 1884–1976) developed improved photoelectric cells and also electroluminescent semiconductor devices, the direct forerunners of light emitting diodes (LEDs), during the period 1919–1923 (pp. 1104, 1106). After that time, both Gudden and Pohl separately continued to conduct research on advanced semiconductor devices and microelectronics through World War II, including developing prototype transistors.

Karl Ferdinand Braun (1850–1918) invented semiconductor diodes (1874), improved radio transmitters and receivers (1897), cathode ray tubes and oscilloscopes (1897), phased array antennas (1905), etc.

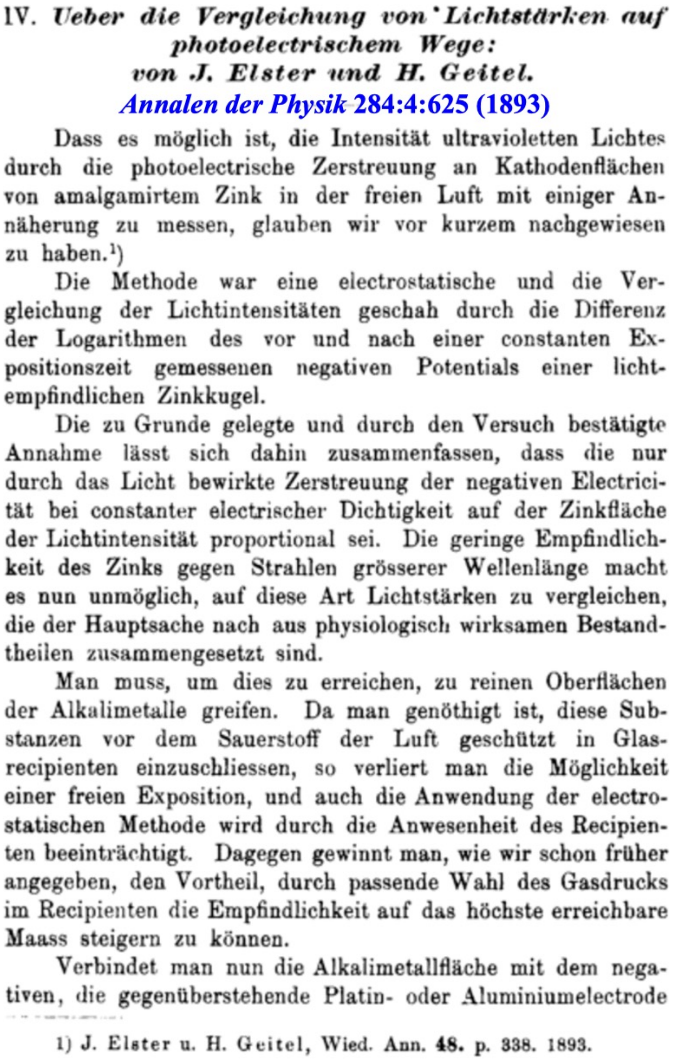
Julius Elster (left, 1854–1920) and Hans Geitel (right, 1855–1923) invented the photoelectric cell (1893)



IV. ***Ueber die Vergleichung von Lichtstärken auf photoelectrischem Wege;***
von J. Elster und H. Geitel.
Annalen der Physik 284:4:625 (1893)

Dass es möglich ist, die Intensität ultravioletten Lichtes durch die photoelectrische Zerstreuung an Kathodenflächen von amalgamirtem Zink in der freien Luft mit einiger Annäherung zu messen, glauben wir vor kurzem nachgewiesen zu haben.[1])

Die Methode war eine electrostatische und die Vergleichung der Lichtintensitäten geschah durch die Differenz der Logarithmen des vor und nach einer constanten Expositionszeit gemessenen negativen Potentials einer lichtempfindlichen Zinkkugel.

Die zu Grunde gelegte und durch den Versuch bestätigte Annahme lässt sich dahin zusammenfassen, dass die nur durch das Licht bewirkte Zerstreuung der negativen Electricität bei constanter electrischer Dichtigkeit auf der Zinkfläche der Lichtintensität proportional sei. Die geringe Empfindlichkeit des Zinks gegen Strahlen grösserer Wellenlänge macht es nun unmöglich, auf diese Art Lichtstärken zu vergleichen, die der Hauptsache nach aus physiologisch wirksamen Bestandtheilen zusammengesetzt sind.

Man muss, um dies zu erreichen, zu reinen Oberflächen der Alkalimetalle greifen. Da man genöthigt ist, diese Substanzen vor dem Sauerstoff der Luft geschützt in Glasrecipienten einzuschliessen, so verliert man die Möglichkeit einer freien Exposition, und auch die Anwendung der electrostatischen Methode wird durch die Anwesenheit des Recipienten beeinträchtigt. Dagegen gewinnt man, wie wir schon früher angegeben, den Vortheil, durch passende Wahl des Gasdrucks im Recipienten die Empfindlichkeit auf das höchste erreichbare Maass steigern zu können.

Verbindet man nun die Alkalimetallfläche mit dem negativen, die gegenüberstehende Platin- oder Aluminiumelectrode

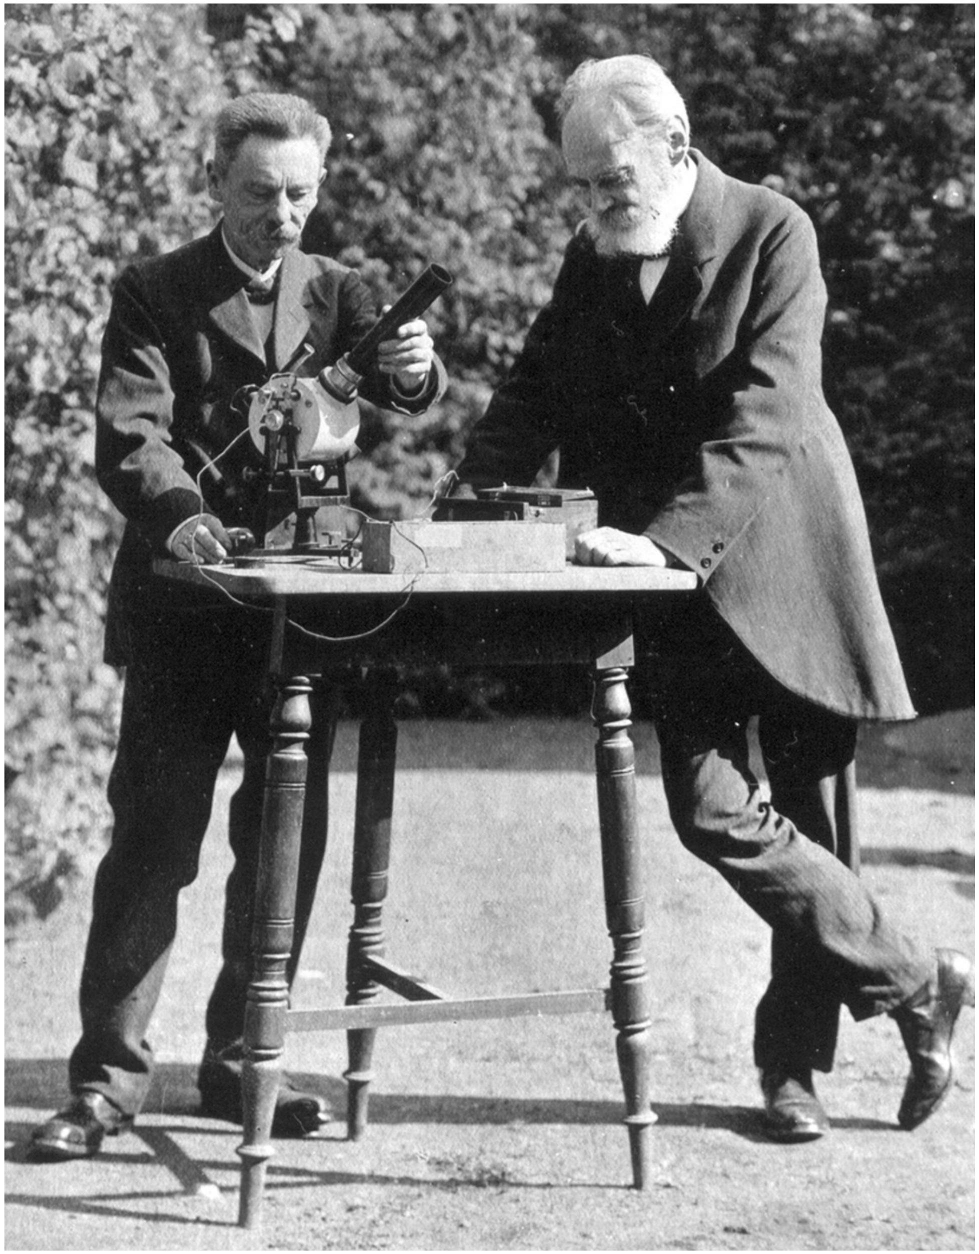

Figure 6.71: Julius Elster and Hans Geitel invented the photoelectric cell in 1893.

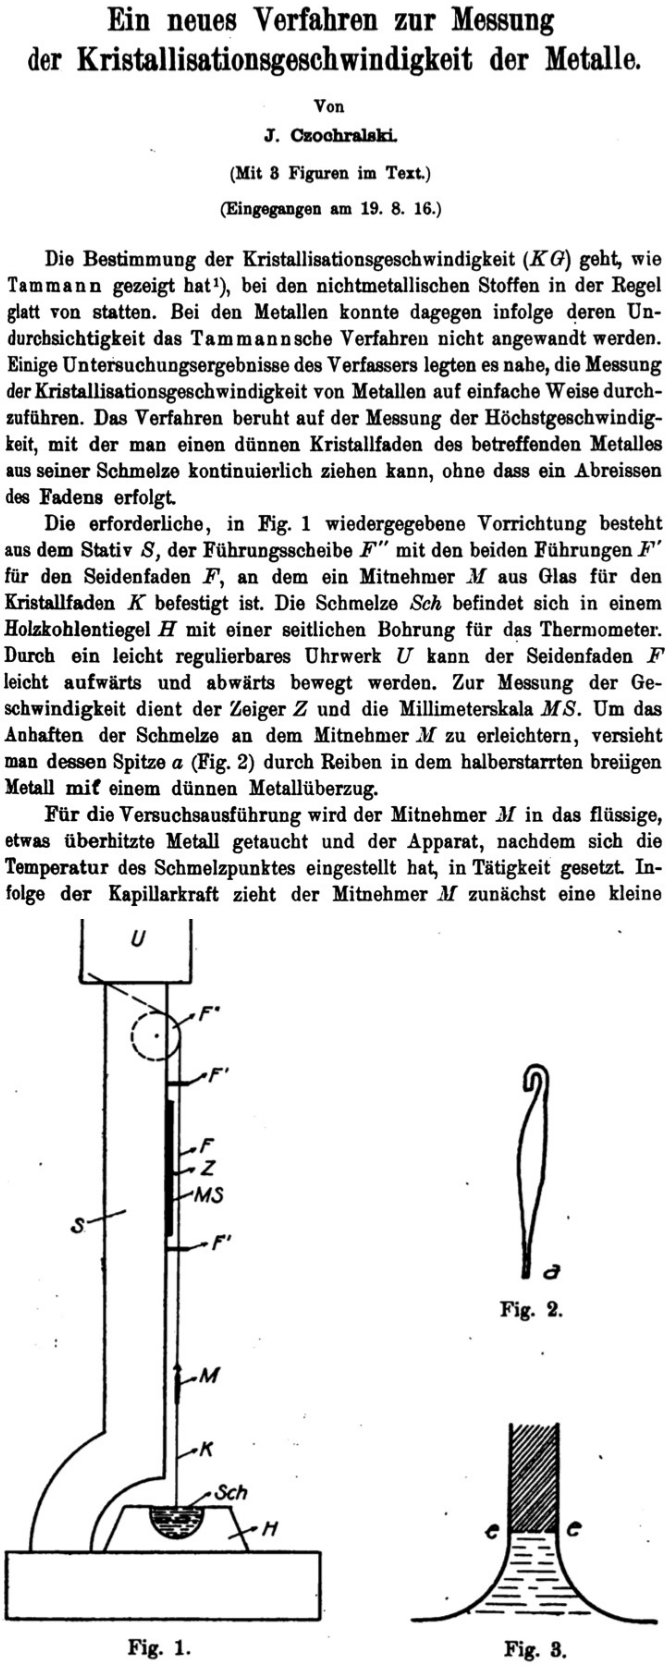
Jan Czochralski (1885–1953)
Method for growing semiconductor crystals/wafers (1916)



Ein neues Verfahren zur Messung der Kristallisationsgeschwindigkeit der Metalle.

Von

J. Czochralski.

(Mit 3 Figuren im Text.)

(Eingegangen am 19. 8. 16.)

Die Bestimmung der Kristallisationsgeschwindigkeit (*KG*) geht, wie Tammann gezeigt hat[1]), bei den nichtmetallischen Stoffen in der Regel glatt von statten. Bei den Metallen konnte dagegen infolge deren Undurchsichtigkeit das Tammannsche Verfahren nicht angewandt werden. Einige Untersuchungsergebnisse des Verfassers legten es nahe, die Messung der Kristallisationsgeschwindigkeit von Metallen auf einfache Weise durchzuführen. Das Verfahren beruht auf der Messung der Höchstgeschwindigkeit, mit der man einen dünnen Kristallfaden des betreffenden Metalles aus seiner Schmelze kontinuierlich ziehen kann, ohne dass ein Abreissen des Fadens erfolgt.

Die erforderliche, in Fig. 1 wiedergegebene Vorrichtung besteht aus dem Stativ *S*, der Führungsscheibe F'' mit den beiden Führungen F' für den Seidenfaden *F*, an dem ein Mitnehmer *M* aus Glas für den Kristallfaden *K* befestigt ist. Die Schmelze *Sch* befindet sich in einem Holzkohlentiegel *H* mit einer seitlichen Bohrung für das Thermometer. Durch ein leicht regulierbares Uhrwerk *U* kann der Seidenfaden *F* leicht aufwärts und abwärts bewegt werden. Zur Messung der Geschwindigkeit dient der Zeiger *Z* und die Millimeterskala *MS*. 6.5.3 Transistors

According to official histories, the first transistor was invented at Bell Laboratories in late 1947 and early 1948 by John Bardeen (American, 1908–1991), Walter Brattain (American, 1902–1987), and William Shockley (American, 1910–1989). However, there is significant evidence that at least 12 different groups of German-speaking scientists may have invented transistors earlier:

1. Julius Edgar Lilienfeld (Austrian, 1882–1963) invented an improved X-ray tube in 1912, the field effect transistor in 1925, and an improved electrolytic capacitor in 1931, as shown on pp. 1084–1052 and 2657–2677. Lilienfeld filed several patent applications on his field effect transistor during the period 1925–1928. The great level of detail in those applications regarding the production and performance of such transistors suggests that he built and tested them [Arns 1998; Crawford 1991], although exactly what results he achieved are not clear from currently available documents. Much later, Bell Laboratories secretly built functioning devices based directly on Lilienfeld's patents, lending further support to the view that the patents were based on Lilienfeld's own successful experimentation [Arns 1998; Shockley and Pearson 1948]. In the 1920s Lilienfeld moved to the United States, where he married an American woman. It appears that he was unsuccessful in finding sufficient support for his transistor idea in the United States. In the 1930s Lilienfeld and his wife moved to the island of Saint Thomas in the Caribbean, where they lived the rest of their lives.

2. Oskar Heil (German, 1908–1994) filed a detailed patent application on field effect transistors in 1934; see pp. 1054 and 2679–2681. Currently it is unclear just what experimental work Heil may have done on the concept either before or after filing the patent application, or whether other German-speaking scientists may have taken up the ideas proposed in the application.

3. Gilles Holst (Dutch, 1886–1968) and Willem Christiaan van Geel (Dutch, 1895–1967) filed a German patent application on transistors in 1935. See pp. 1056–1057 and 2686–2689. Holst was the research director at the Philips Eindhoven laboratory [Van Delft 2014], and van Geel was an expert there on metal and semiconductor materials. Both were nominated for the Nobel Prize in Physics but never won.[12] Holst was also one of the inventors of the sodium vapor lamp in 1932 (p. 971). Philips Eindhoven was closely tied to the rest of the predominantly German-speaking research world from the late nineteenth century through World War II, including work on electronics, communications, and directed energy beams.[13] More archival research is needed to determine how far the work of Holst and van Geel got by 1945, or how much it was influenced by or influenced transistor-related work by other research groups.

[13] See for example: CIOS III-1; CIOS VI-26, 27; CIOS X-13; CIOS XI-10; CIOS XII-22.

4. Rudolf Hilsch (German, 1903–1972) and Robert Pohl demonstrated a proof-of-concept point-contact transistor in 1938 [Hilsch and Pohl 1938]. As shown on pp. 1058 and 2691–2692, like a modern transistor, this solid-state semiconductor device had three electrodes, with the current flow into the middle electrode (the base, in modern terminology) controlling and greatly amplified by the much larger current flow between the other two electrodes. For the 1938 experiments, that signal amplification was approximately a factor of 20. These results were extremely impressive, but the reason they are best described as "proof of concept" is that they were obtained in a material (a potassium bromide crystal) that became a good semiconductor only at a very high temperature (490^{o}C) and voltages (100–150 Volts), which would not be practical for use in normal electronic circuits.

Hilsch recognized those limitations and promptly proposed that the results be replicated by modifying existing room-temperature semiconductor diodes to add a third electrode for the base [Hilsch 1939]:

> Durch diese Messung ist zum erstenmal gezeigt worden, daß man auch in festen Körpern Ströme steuern kann. Die Trägheit der Ströme in diesem "großen" Modell ist naturgemäß groß. Es ist jetzt nur eine Aufgabe der Technik, auch in den dünnen Sperrschichten der technischen Gleichrichter das Steuergitter unterzubringen. Wenn die Lösung dieser Aufgabe gelingt, kann der Dreielektroden-Kristall auch technisch neben dem Dreielektroden-Rohr seine Bedeutung erhalten.

> This measurement has shown for the first time that it is also possible to control currents in solid bodies. The inertia of the currents in this "large" model is naturally large. It is now only a technical task to add the control grid in the thin barrier layers of engineering rectifiers. If the solution to this problem is successful, the three-electrode crystal can also gain technical significance alongside the three-electrode tube.

From available documentation, it is unclear exactly what projects Hilsch worked on between 1939 and the post-war period. Given his determination to replicate the transistor amplifier results in a more practical semiconductor device, and given the extensive wartime work on new and improved semiconductor devices, it seems likely that he would have carried his transistor work further, or collaborated with other scientists to do so. In any event, the 1938 Hilsch and Pohl paper and the 1939 Hilsch paper were published in physics journals that were highly regarded and widely read in the German-speaking world, so they would have encouraged many other scientists (such as those listed below) to try to replicate and extend that work.

5. Erich Habann (German, 1892–1968) filed a very detailed patent application on point-contact transistors, their fabrication, and use in 1942 (pp. 1060 and 2695–2699). The level of detail suggests that Habann may well have already produced and demonstrated such transistors at his Hessenwinkel laboratory. Although documentation on his results is not currently available, it is known that Habann worked on a number of secretive research projects during the war and was well funded by the German military [Nagel 2006].

6. Walter Schottky (Swiss/German, 1886–1976) published detailed analyses of semiconductor properties necessary for transistors in 1942 [Handel 1999]. See pp. 1062 and 2701–2709. All of Schottky's papers were seized by the United States in 1945 and never returned to him or publicly disclosed.

7. Heinrich Welker (German, 1912–1981) and Herbert Mataré (German, 1912–2011) began developing a point-contact transistor in Germany during the war, filed a detailed patent application based on that wartime work on 6 April 1945, and publicly announced their transistor in 1948 in France.[14] See pp. 1064 and 2711–2720.

8. Erwin Weise (German?, 19??–19??) admitted to Allied investigators that he "had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes" to create "electronic amplifiers without vacuum" (pp. 1066 and 2722–2733).

9. Frank Rose (German?, 19??–19??), Eberhard Spenke (German, 1905–1992), and Erich Waldkötter (German?, 19??–19??) filed detailed patent applications on transistors in 1949, as shown on pp. 1068 and 2735–2744. Because of the extreme political and financial restrictions on conducting research in Germany after the war, it seems likely that their patent applications were based on wartime work [Handel 1999]. Indeed, large numbers of patent applications on wartime inventions were filed in 1949 when the West German patent office opened.

10. Karl Seiler (German, 1910–1991) and Paul Ludwig Günther (German, 1892–1969) developed methods for designing and fabricating silicon semiconductor devices throughout the war and into the postwar period (pp. 1070 and 2746–2754). Their work was applied to transistors after the war, and it may have been used for that purpose during the war [Handel 1999].

11. Helmar Frank (Moravian, 1919–2015) and Jan Tauc (Bohemian, 1922–2010) worked in very large, secret, German-run laboratories in Tannwald (now Tanvald, Czech Republic) during the war [Lojek 2007]. When Czechoslovakia salvaged what was left of those laboratories and restarted them after the war, one of the first actions that Frank and Tauc carried out was to produce and demonstrate transistors. Those postwar Czech transistors were based at least in part, and quite possibly entirely, on wartime German work (pp. 1072, 2756–2757, 3983, 5503, 5513, and 5549). Both Frank and Tauc continued to develop semiconductor and microelectronics technologies in Czechoslovakia for many years. Frank was interrogated by the United States in 1945 regarding his knowledge of advanced electronics technologies. Tauc eventually moved to the United States.

---

[14] Handel 1999; Ringer and Welker 1948; Riordan 2005; Van Dormael 2004, 2009, 2012.

12. During the war, Bernhard Gudden (German, 1892–1945) and Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) ran a secretive and well-funded group that was developing advanced semiconductor devices at Charles University in Prague [Lojek 2007]. After the war, Gudden refused to assist Russian or Russian-backed forces and died in a Czech prison. Lehovec was extensively interrogated by the United States and then moved to the United States, where he filed patents on light emitting diodes, transistors, and integrated circuits. His first U.S. patent application on transistors covered a design that had several advantages over the transistors from Bell Laboratories, and that may well have been based on wartime work that he and Gudden had been conducting. See pp. 1074, 1097, 2757–2763, 2818–2832, and 2895–2910.

In addition to these 12 groups, were there any other German-speaking groups developing transistors, for example at laboratories run by AEG, Askania, Blaupunkt, Fernseh, Loewe Radio, C. Lorenz, Philips, the Reichspost, Siemens, the SS, Telefunken, various universities, or other laboratories in Germany, Austria, Czech territory, Polish territory, or elsewhere? Much more archival research is needed.

Patented Jan. 28, 1930 **1,745,175**

UNITED STATES PATENT OFFICE

JULIUS EDGAR LILIENFELD, OF BROOKLYN, NEW YORK

METHOD AND APPARATUS FOR CONTROLLING ELECTRIC CURRENTS

Application filed October 8, 1926, Serial No. 140,363, and in Canada October 22, 1925.

The invention relates to a method of and apparatus for controlling the flow of an electric current between two terminals of an electrically conducting solid by establishing a third potential between said terminals; and is particularly adaptable to the amplification of oscillating currents such as prevail, for example, in radio communication. Heretofore, thermionic tubes or valves have been generally employed for this purpose; and the present invention has for its object to dispense entirely with devices relying upon the transmission of electrons thru an evacuated space and especially to devices of this character wherein the electrons are given off from an incandescent filament. The invention has for a further object a simple, substantial and inexpensive relay or amplifier not involving the use of excessive voltages, and in which no filament or equivalent element is present. More particularly, the invention consists in affecting, as by suitable incoming oscillations, a current in an electrically conducting solid of such characteristics that said current will be affected by and respond to electrostatic changes. Means are associated with the aforesaid conducting solid whereby these electrostatic changes are set up conformably with the incoming oscillations which are thus reproduced greatly magnified in the circuit, suitable means being provided, also, to apply a potential to the said conducting solid portion of the amplifier circuit as well as to maintain the electrostatic producing means at a predetermined potential which is to be substantially in excess of a potential at an intermediate point of said circuit portion.

The nature of the invention, however, will best be understood when described in connection with the accompanying drawings, in which—

Fig. 1 is a perspective view, on a greatly enlarged scale and partly in section, of the novel apparatus as embodied by way of example in an amplifier.

Fig. 2 is a diagrammatic view illustrating the voltage characteristics of an amplifier as shown in Fig. 1.

Fig. 3 is a diagrammatic view of a radio receiving circuit in which the novel amplifier is employed for two stages of radio frequency and two of audio frequency amplification.

Referring to the drawings, 10 designates a base member of suitable insulating material, for example, glass; and upon the upper surface of which is secured transversely thereof and along each side a pair of conducting members 11 and 12 as a coating of platinum, gold, silver or copper which may be provided over the glass surface by well-known methods such as chemical reduction, etc. It is desirable that the juxtaposed edges of the two terminal members 11 and 12 be located as closely as possible to each other; and substantially midway of the same there is provided an electrode member 13, which is of minimum dimensions to reduce capacity effect. This member consists of a suitable metal foil, preferably aluminum foil, and may conveniently be secured in position by providing a transverse fracture 14 in the glass and then reassembling the two pieces to retain between the same the said piece of aluminum foil of a thickness approximating one ten-thousandth part of an inch. The upper edge of this foil is arranged to lie flush with the upper surface of the glass 10.

Over both of the coatings 11 and 12, the intermediate upper surface portion of the glass 10, and the edge of the foil 13 is provided a film or coating 15 of a compound having the property of acting in conjunction with said metal foil electrode as an element of uni-directional conductivity. That is to say, this coating is to be electrically conductive and possess also the property, when associated with other suitable conductors, of establishing at the surface of contact a considerable drop of potential. The thickness of the film, moreover, is minute and of such a degree that the electrical conductivity therethru would be influenced by applying thereto an electrostatic force. A suitable material for this film and especially suitable in conjunction with aluminum foil, is a compound of copper and sulphur. A convenient way of providing the film over the coatings

HAUPTPATENT

Dr. Oskar HEIL, Berlin-Grunewald (Deutschland).

Verfahren zum Steuern oder Verstärken elektrischer Ströme.

Die vorliegende Erfindung betrifft ein Verfahren und eine Vorrichtung zum Steuern oder Verstärken elektrischer Ströme.

Während man bisher zu diesem Zweck fast ausschließlich Elektronenröhren verwendet hat, beruht das erfindungsgemäß beanspruchte Verfahren auf einem ganz neuen Effekt, der zum ersten Mal beobachtet wurde.

Es wurde festgestellt, daß dünne Schichten von Halbleitern ihren Widerstand für den elektrischen Strom in weiten Grenzen ändern, wenn man diese Schichten als Elektroden von Kondensatoren ausbildet und die Elektroden auf verschiedene Spannung auflädt.

Zur näheren Erläuterung diene die schematische beispielsweise Darstellung in Fig. 1. Zwischen den Metallelektroden 1 und 2 befindet sich die dünne Schicht des Halbleiters 3. Die Batterie 4 schickt einen Strom durch die dünne Halbleiterschicht, der mittels Amperemeter 5 gemessen wird. Lädt man nun die Elektrode 6 positiv oder negativ gegenüber der Schicht 3 auf, so ändert sich der elektrische Widerstand dieser Schicht und damit auch die am Amperemeter 5 gemessene Stromstärke. Es ist also möglich, durch Anlegen einer irgendwie geformten Wechselspannung an die Klemmen 7 den Strom in 5 zu steuern. Mit solchen Anordnungen lassen sich in ähnlicher Weise wie mit Elektronenröhren Verstärker bauen. Es ist vorteilhaft, den Abstand zwischen der Elektrode 6 und dem Halbleiter 3 möglichst gering zu machen, etwa durch Verwendung einer dünnen Isolierschicht von weniger als $^1/_{100}$ mm Dicke zwischen beiden. Zweckmäßigerweise findet dabei ein Isoliermaterial von hoher Dielektrizitätskonstante Anwendung (mit einem Zahlenwert von 10 oder darüber).

Statt eine Steuerelektrode 6 kann man auch zwei Steuerelektroden 6 zu beiden Seiten der Schicht 3 anordnen; statt dessen können solche auch nur auf einer Seite angebracht werden. Man kann sie in diesem Falle nebeneinander oder hintereinander, bezogen auf die Stromrichtung im Halbleiter, be-

ELECTRODE SYSTEM OF UNSYMMETRICAL CONDUCTIVITY

Gilles Holst and Willem Christiaan van Geel, Eindhoven, Netherlands, assignors to N. V. Philips' Gloeilampenfabrieken, Eindhoven, Netherlands

Application March 4, 1936, Serial No. 67,052
In Germany March 9, 1935

3 Claims. (Cl. 179—171)

The invention relates to an electrode system of unsymmetrical conductivity formed by two layers of different emitting capacity which are separated from one another by a layer of insulating material.

It is known already that if cuprous oxide rectifiers form the starting point, a three-electrode system may be produced by providing in the semi-conductive oxide layer a grid to which an auxiliary voltage is applied in order to act upon the electron current flowing from the copper electrode to the semi-conductor. Experiments have shown, however, that a detector thus produced does not function satisfactorily.

Furthermore, it has previously been proposed to form a detector as a dry rectifier in which the electron current between the metallic electrode and the semi-conductor is acted upon by the field variation of a magnetic circuit of which the rectifier forms a part. This form of construction has the drawback that it takes up much room and cannot be operated in a simple manner.

The invention has for its object to provide a detector or amplifier capable of taking the place of the present valves with thermal emission which are complicated and expensive in initial cost as well as in operation, for example, due to the current consumption for heating the cathode.

According to the invention, an electrode system of unsymmetrical conductivity is formed by two layers of different emitting capacity which are separated from one another by a layer of insulating material, and embedded in the insulating intermediate layer is a grid provided with a supply conductor for applying potentials for the control of the electron current and/or for screening purposes.

A detector of this kind may consequently take the place of a usual detector or three-electrode-amplifying valve for it likewise comprises both an emitting electrode and an electrode which does not or substantially does not emit and, between these two electrodes, a grid which corresponds to a grid arranged in a valve in the vacuum between the cathode and the anode. In accordance with the invention, the grid is located in the insulating layer, which, as has been found, has the most favorable result. It is clear that the number of grids need not be limited to one.

A favorable form of execution of an electrode system according to the invention is that which follows:

The grids are constituted by perforated layers of conductive material which are contained in the insulating intermediate layer, said perforated layers being obtained, for example, by applying to one of the electrodes alternately an insulating layer and a perforated conductive layer and finally to the last conductive layer again an insulating layer. It is consequently possible to form electrode systems which correspond to the present radio valves having three or more electrodes such as, for example, the triodes, tetrodes, pentodes, hexodes, etc.

It is particularly important and advantageous that the insulating intermediate layer which contains the grids be formed independently of the adjacent electrode layers, for this renders it possible to control at will both the thickness of the layer and the position of the grids. The intermediate layer may be constituted of, for example, artificial resin which is applied in liquid condition to one of the electrodes. It is thus possible to apply a perfectly homogeneous layer.

It is of course very desirable to make the intermediate layer as thin as possible in order to raise as much as possible the electrical field strength between the main electrodes, as this has a great effect on the favorable operation. Due to the presence of a conductive grid there arises however the possibility that due to the too slight thickness of the insulating layer at a single, for example, accidentally projecting point, said grid may short-circuit one of the electrodes. In one favorable form of execution the risk of a short circuit is avoided by providing the grids with an insulating coating before they are applied to the insulating layer.

When choosing a grid material it should be considered that on account of its own emission a grid of emitting material acts upon the electron current between the anode and the cathode. According to a favorable mode of execution use is therefore made of a grid material being a semi- or bad conductor and having a slight emitting capacity.

The invention will be explained more fully with reference to the accompanying drawing which represents, by way of example, one embodiment thereof.

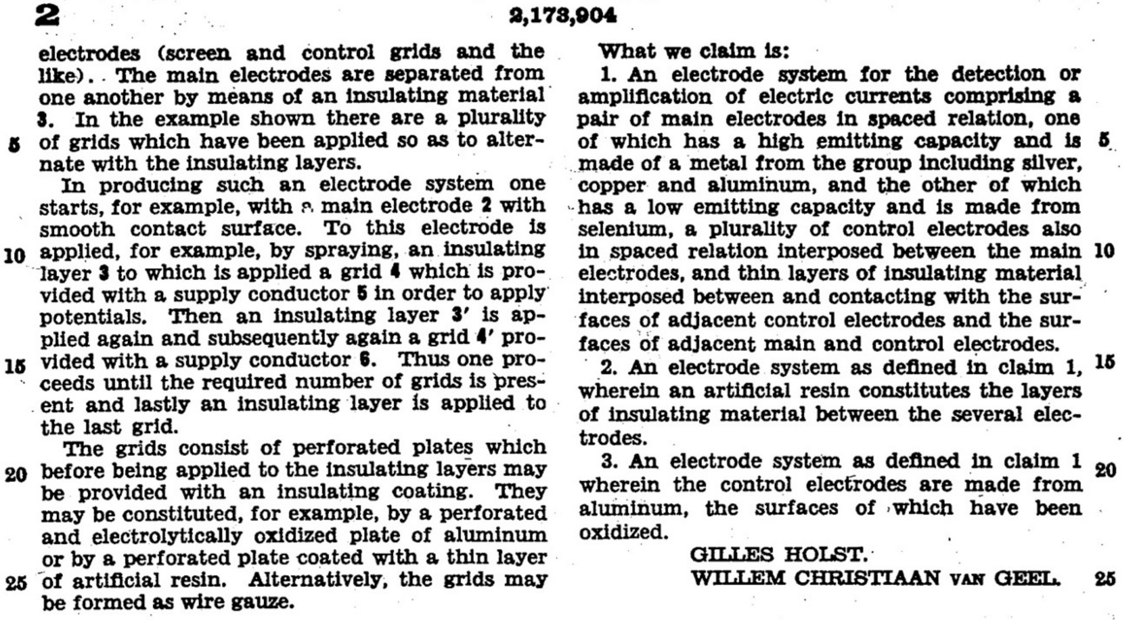
The main electrodes **1** and **2** are formed, respectively, by a conductor consisting of a metal of high emitting capacity such as aluminum, copper or silver and by a semi-conductor as is usual in dry rectifiers. Selenium is a very suitable material for the semi-conductor.

The drawing represents, by way of example, a six-electrode-system. Besides the main electrodes **1** and **2** there are consequently four further

Figure 6.77: Gilles Holst and Willem Christiaan van Geel filed a patent application on transistors in 1935.

Transistors (3)

Gilles Holst and Willem Christiaan van Geel filed a patent application on transistors (1935)



2 2,173,904

electrodes (screen and control grids and the like). The main electrodes are separated from one another by means of an insulating material 3. In the example shown there are a plurality of grids which have been applied so as to alternate with the insulating layers.

In producing such an electrode system one starts, for example, with a main electrode 2 with smooth contact surface. To this electrode is applied, for example, by spraying, an insulating layer 3 to which is applied a grid 4 which is provided with a supply conductor 5 in order to apply potentials. Then an insulating layer 3' is applied again and subsequently again a grid 4' provided with a supply conductor 6. Thus one proceeds until the required number of grids is present and lastly an insulating layer is applied to the last grid.

The grids consist of perforated plates which before being applied to the insulating layers may be provided with an insulating coating. They may be constituted, for example, by a perforated and electrolytically oxidized plate of aluminum or by a perforated plate coated with a thin layer of artificial resin. Alternatively, the grids may be formed as wire gauze.

What we claim is:

1. An electrode system for the detection or amplification of electric currents comprising a pair of main electrodes in spaced relation, one of which has a high emitting capacity and is made of a metal from the group including silver, copper and aluminum, and the other of which has a low emitting capacity and is made from selenium, a plurality of control electrodes also in spaced relation interposed between the main electrodes, and thin layers of insulating material interposed between and contacting with the surfaces of adjacent control electrodes and the surfaces of adjacent main and control electrodes.

2. An electrode system as defined in claim 1, wherein an artificial resin constitutes the layers of insulating material between the several electrodes.

3. An electrode system as defined in claim 1 wherein the control electrodes are made from aluminum, the surfaces of which have been oxidized.

Robert Pohl (1884–1976)

Rudolf Hilsch (1903–1972)

Hilsch and Pohl demonstrated a proof-of-concept point-contact transistor with 20x signal amplification (1938).

KBr semiconductor crystal only worked at high temperature (490^{o}C) and voltages (100-150 Volts).

Hilsch proposed that the results be replicated by modifying existing room-temperature semiconductor diodes to add a third electrode for the base.

Rudolf Hilsch. 1939. Elektronenleitung in Kristallen. *Die Naturwissenschaften* 27:489-492:

“This measurement has shown for the first time that it is also possible to control currents in solid bodies. The inertia of the currents in this ‘large’ model is naturally large. It is now only a technical task to add the control grid in the thin barrier layers of engineering rectifiers. If the solution to this problem is successful, the three-electrode crystal can also gain technical significance alongside the three-electrode tube.”

What did Hilsch and Pohl work on 1938–1945? At the very least, their 1938 paper inspired other German-speaking scientists.

Figure 6.80: Rudolf Hilsch and Robert Pohl demonstrated a prototype point-contact transistor in 1938 [Hilsch and Pohl 1938].

Einrichtung zur Verstärkung elektrischer Ströme und Spannungen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 22. September 1942 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 1951)

Patentanmeldung bekanntgemacht am 20. August 1953
Patenterteilung bekanntgemacht am 12. März 1959

Die Erfindung benutzt zur Verstärkung elektrischer Ströme oder Spannungen einen Trockengleichrichter. Dieser besteht z. B. beim Selentrockengleichrichter aus Selen in kristallisiertem Zustande als Halbleiter, das sich als dünne Schicht zwischen zwei Elektroden befindet, die bei gleicher Feldstärke als Kathoden verschieden große Elektronenströme in das Selen hineinzusenden vermögen. Je unterschiedlicher die beiden Elektroden in ihrer Emissionsfähigkeit sind, desto besser arbeitet der Gleichrichter. In der Praxis wird Selen bei so hoher Temperatur auf einer Nickelunterlage geschmolzen, daß sich zwischen dem Nickel und dem Selen eine dünne Schicht von Nickelselenid bildet. Dieses Nickelselenid vermag als Kathode nur sehr geringe Elektronenmengen in das Selen zu emittieren, im Gegensatz zu den Metallen wie Cadmium, Blei, die als Kathoden bei gleich großer Feldstärke erheblich größere Elektronenmengen in das Selen hineinzusenden vermögen. Die Metalle selbst unterscheiden sich im übrigen nur wenig in ihrem Emissionsvermögen untereinander. Eine Selenschicht, die sich zwischen einer Nickelselenidelektrode auf der einen Seite und einer Metallelektrode auf der andern Seite befindet, wird große Ströme hindurchlassen, wenn die Metallelektrode Kathode ist, und nur sehr geringe Ströme hindurchlassen, wenn die Nickelselenidelektrode Kathode ist.

Die Erfindung geht von diesen Erkenntnissen aus. Sie geht ferner von der Erkenntnis aus, daß der Strom in der Selenschicht ein reiner Elektronenstrom ist, daß dieser außer von der Elektronenemissionsfähigkeit der anliegenden Kathode von der elektrischen Feldstärke abhängt, die an dieser Kathode herrscht, und daß demgemäß die Verhältnisse ähnlich liegen wie bei Hochvakuumröhren mit Glühkathode. Infolgedessen muß sich mit dem Trockengleichrichter auch ein Verstärker analog den Glühkathoden-Verstärkerröhren zusammenbauen lassen. Da wegen der dünnen Selenschicht der an sich bekannte Einbau eines Gitters nicht zum gewünschten Ziel führt, wird die eine Elektrode erfindungsgemäß unterteilt, derart, daß der eine Teil als Steuerorgan dient und aus einem Metall besteht, das mit der Gleichrichterschicht durch chemische Reaktion eine Übergangsschicht bildet. Grundsätzlich ist es möglich, dieses Steuerorgan entweder auf der Anodenseite unterzubringen oder, wie in der Zeichnung, auf der Kathodenseite. Die beiden Elektroden a und b liegen hier in einer Ebene auf derselben Seite der Selenschicht, während auf der andern Seite der Selenschicht die Anode A anhaftet. a ist die Steuerelektrode und entspricht dem Gitter in den Verstärkerröhren, b ist die Emissionskathode und entspricht dem Glühfaden in Verstärkerröhren. Damit die von der Steuerelektrode ausgehenden elektrischen Kraftlinien sich möglichst zwischen Emissionskathode b und Steuerelektrode a ausbilden und weniger zwischen Steuerelektrode a und Anode A, verdient die Anordnung gemäß der Zeichnung den Vorzug vor einer Anordnung des Steuerorgans auf der Anodenseite. Außerdem werden in der Zeichnung die Steuerelektrode a und die Emissionskathode b in Streifen rasterartig ineinandergeschachtelt, wobei möglichst keiner der Streifen breiter gehalten wird, als die Selenschicht dick ist. Die Streifen a werden unter sich elektrisch verbunden, und ebenso sind die Streifen b unter sich elektrisch verbunden. Die Streifen sind durch dünne Isolationsblättchen (Glimmer) voneinander gegen seitliche Berührung isoliert. Die Anode A stellt in üblicher Weise eine zusammenhängende Fläche aus einem aufgespritzten oder angepreßten Metall dar.

Die Verstärkung hängt hauptsächlich von dem Verhältnis der Oberflächen der Streifen der Emissionskathode zu denen des Steuerorgans ab. Natürlich kommen die Oberflächen nur so weit in Betracht, als die Emissionskathode und die Steuerelektrode die Selenschicht tatsächlich berühren. Das Verhältnis spielt eine ähnliche Rolle wie der Durchgriff bei Verstärkerröhren: je kleiner das angegebene Verhältnis ist, desto größer ist der Verstärkungsgrad. Die Schaltung ist der der Verstärkerröhren analog: Der zu verstärkende Strom wird zwischen Emissionskathode b und Steuerelektrode a gelegt. Der verstärkte Strom wird zwischen Emissionskathode b und Anode A abgenommen. Zwischen der Kathode b und der Anode A liegt ständig eine entsprechend bemessene Gleichspannung, und zwar mit dem negativen Pol an der Emissionskathode b und mit dem positiven Pol an der Anode A. Die Steuerelektrode a muß eine negative Gleichspannung vorgespannt erhalten, ähnlich der negativen Vorspannung der Gitter bei Verstärkerröhren. Diese Gleichspannung — ebenfalls optimal bemessen — liegt also mit dem negativen Pol an der Steuerelektrode a und mit dem positiven Pol an der Emissionskathode b.

Eine solche Einrichtung würde auf der Steuerseite noch zuviel Energie verbrauchen, als Verstärker also noch wenig oder gar nicht funktionieren. Die Steuerelektrode a wird nun aus einem Material angefertigt, das möglichst schlecht Elektronen in die Gleichrichterschicht (Se) emittiert, z. B. Nickelselenid, während die Emissionskathode b aus einem Material hergestellt wird, das möglichst gut und reichlich Elektronen in die Gleichrichterschicht emittiert (praktisch alle Metalle). Unter den hier möglichen Metallen kommen besonders diejenigen in Betracht, die sich nicht mit Selen verbinden. Dies sind außer Graphit Chrom und Aluminium. Das Material der Anode ist gleichgültig. Zweckmäßig besteht es aus Blei oder Cadmium oder Zinn oder einer leicht aufspritzbaren Metallegierung.

Der Raster wird aus entsprechend geschnittenen Streifen, aus dünnem Nickelblech für die Steuerelektrode a und aus dünnen Aluminiumfolien für die Emissionskatode b, gebildet. Die der Selenschicht zugekehrte Fläche der Streifen wird möglichst eben gemacht. Auf ihr wird Selen in etwa 1/10 bis 2/10 mm dicker Schicht zum Schmelzen gebracht. Die Fläche mit der Selenschicht wird dann so hoch erhitzt, bis das Nickel mit dem Selen reagiert und eine oberflächliche Nickelselenidschicht bildet, aber nicht so hoch erhitzt, daß auch das Aluminium reagiert (300° C genügen). Die Erhitzung erfolgt so lange, bis sich die Nickeloberfläche vollständig mit der Nickelselenidschicht von ausreicher Dicke bedeckt hat. Darauf wird die Schicht bei 200° C oder besser durch Abschrecken zum Erstarren gebracht. Dann wird zweckmäßig mit einem Graphit- oder Aluminiumstempel die Selenschicht fest an ihre gerasterte Unterlage gepreßt und mehrere Stunden unter diesem Preßdruck bei etwa 120° C und dann bei 210° C angelassen. Schließlich wird auf die fertige und abgekühlte Schicht nach Entfernung des Druckstempels eine leicht schmelzende Metallegierung, z. B. aus Cadmium und Zinn, als Anode A aufgespritzt oder auch nur eine Bleiplatte als Anode A gegen die Selenschicht gepreßt. Für die Selenschicht ist eine bestimmte Dicke optimal. Ist sie zu dick, so spielen die Unterschiede in der Elektronenemissionsfähigkeit der anliegenden Elektroden nicht mehr die entscheidende Rolle. Der Strom wird dann hauptsächlich von der Eigenleitfähigkeit des Selens bestimmt. Bei zu dünner Schicht leidet die Durch-

(Mitteilung aus der Zentralabteilung der Siemens & Halske A.-G., Berlin-Siemensstadt.)

Vereinfachte und erweiterte Theorie der Randschichtgleichrichter.

Von **W. Schottky.**

Mit 14 Abbildungen. (Eingegangen am 27. September 1941.)

1. Die Schicht konstanter Raumladungsdichte. 2. Die allgemeine Strom-Spannungsbeziehung bei Gleichstrom. 3. Verhalten in Sperr- und Flußrichtung. 4. Vergleich mit der strengen Theorie. 5. Die Schicht konstanter Raumladungsdichte bei Wechselstrom. 6. Kapazitätsbeobachtungen an Selengleichrichtern. 7. Zur Frage des Gleichstromverhaltens von Selengleichrichtern. 8. Beobachtete und berechnete Kennlinien von Selengleichrichtern. 9. Bildkraft-Wirkungen bei Selengleichrichtern. 10. Wirkungen der diskreten Raumladungsverteilung in der Randschicht. 11. Verhältnisse bei unvollständiger Störstellendissoziation. 12. Anwendung auf den Kupferoxydulgleichrichter. (Zusammenfassung am Schluß.)

Das genauere Studium der Kupferoxydul- und Selengleichrichter [1]) hat zu der Erkenntnis geführt, daß bei diesen beiden Gleichrichteranordnungen, die bisher als die technisch wichtigsten anzusehen sind, eine völlige Ionisierung der (Defekt-)Elektronen abgebenden Störstellen in einer etwa 10^{-5} cm dicken, unmittelbar an das Gleichrichtermetall angrenzenden Schicht des Halbleiters anzunehmen ist. Ferner hat sich herausgestellt, daß das Gleich- und Wechselstromverhalten dieser Gleichrichter ganz überwiegend durch die Eigenschaften dieser „Erschöpfungsrandschicht" („Durchführung", S. 235) bestimmt ist, während die Schichten, in denen eine unvollkommene Ionisierung der Störstellen oder eine teilweise Kompensation der Störstellenladungen durch (Defekt-)Elektronenladungen vorhanden sind, nur eine geringe Rolle spielen.

Diese Erkenntnis ist nicht nur von physikalischem und technischem Interesse, sondern ermöglicht auch eine stark vereinfachte mathematische Darstellung der für diesen Gleichrichtertyp maßgebenden Erscheinungen;

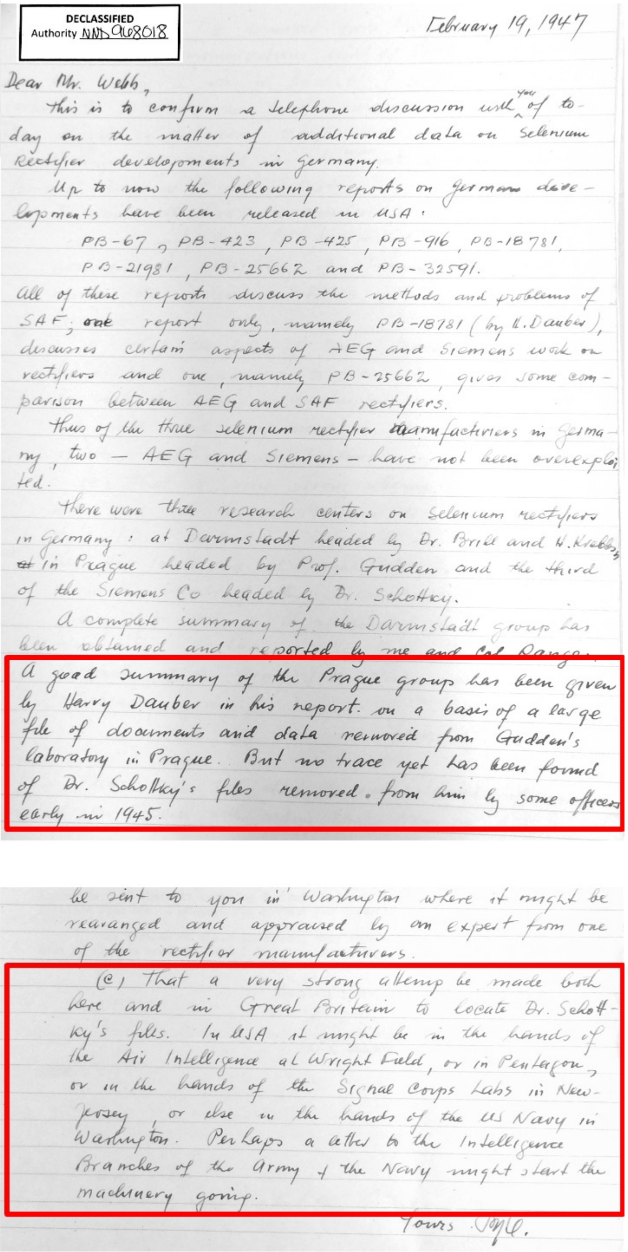
Walter Schottky (1886–1976) published detailed analyses of semiconductor properties necessary for transistors. The U.S. seized all his papers in 1945 and never returned them.



DECLASSIFIED
Authority NND 968018

February 19, 1947

Dear Mr. Webb,

this is to confirm a telephone discussion with you of to-day on the matter of additional data on Selenium Rectifier developments in Germany.

Up to now the following reports on German developments have been released in USA:

PB-67, PB-423, PB-425, PB-916, PB-18781,
PB-21981, PB-25662 and PB-32591.

All of these reports discuss the methods and problems of SAF; ~~one~~ report only, namely PB-18781 (by H. Dauber), discusses certain aspects of AEG and Siemens work on rectifiers and one, namely PB-25662, gives some comparison between AEG and SAF rectifiers.

thus of the three selenium rectifier manufactories in Germany, two – AEG and Siemens – have not been overexploited.

there were three research centers on Selenium rectifiers in Germany: at Darmstadt headed by Dr. Brill and H. Krebbs, ~~at~~ in Prague headed by Prof. Gudden and the third of the Siemens Co headed by Dr. Schottky.

A complete summary of the Darmstadt group has been obtained and reported by me and Col. Range.

A good summary of the Prague group has been given by Harry Dauber in his report. on a basis of a large file of documents and data removed from Gudden's laboratory in Prague. But no trace yet has been found of Dr. Schottky's files removed. from him by some officers early in 1945.

be sent to you in Washington where it might be rearanged and appraised by an expert from one of the rectifier manufacturers.

(c) That a very strong attemp be made both here and in Great Britain to locate Dr. Schottky's files. In USA it might be in the hands of the Air Intelligence at Wright Field, or in Pentagon, or in the hands of the Signal Corps Labs in New-Jersey, or else in the hands of the US Navy in Washington. Perhaps a letter to the Intelligence Branches of the Army + the Navy might start the machinery going.

Yours

Halbleiteranordnung

Patentiert im Gebiet der Bundesrepublik Deutschland vom 2. Oktober 1948 an
Patentanmeldung bekanntgemacht am 21. Dezember 1950
Patenterteilung bekanntgemacht am 24. April 1952

Es sind Anordnungen bekanntgeworden, bei denen ein Störstellenhalbleiter (Germanium) von beispielsweise flachzylindrischer Form so mit Elektroden versehen wird, daß die Grundfläche mit einer großen, im folgenden als *O*-Elektrode bezeichneten Metallelektrode im Kontakt ist, während auf der oberen Fläche eine Metallspitze mit positivem Potential von etwa 1 V gegen die *O*-Elektrode als Steuerelektrode, im folgenden als *G* bezeichnet, dient und eine etwa $^1/_{10}$ mm davon entfernt aufgesetzte Spitze, im folgenden mit *B* bezeichnet, den zu beeinflussenden Strom nach der *O*-Elektrode abführt; die *B*-Elektrode hat hierbei ein negatives Potential von etwa 10 V gegen die *O*-Elektrode.

Die Steuerwirkung derartiger Anordnungen beruht darauf, daß die *G*-Elektrode bei den gewählten Betriebsspannungen einen durch kleine Änderungen von U_g stark variierenden Strom von Defektelektronen in den Halbleiter entsendet, wobei dieser Halbleiter infolge eines gewissen Zusatzes von Elektronen abgebenden Störstellen als Überschußhalbleiter wirkt. Die *B*-Elektrode, die als Kathode gegenüber der *O*-Elektrode geschaltet ist, stößt die Überschußelektroden des Halbleiters ab und vermag, solange kein *G*-Strom fließt, nur dadurch einen Strom zu führen, daß Elektronen aus *B* in den Halbleiter entsendet werden, was bei dem gewählten Halbleiter bedeutend höhere Spannungen erfordert als in umgekehrter Richtung zur Emission von Defektelektronen notwendig sind. Da unter diesen Bedingungen die Elektronenemission von der an der *B*-Elektrode herrschenden Feldstärke abhängt, ist es möglich, diesen Elektronenstrom dadurch zu beeinflussen, daß die von *G* kommenden Defektelektronen teilweise zur Elektrode *B* abfließen; bei den großen Absolutstromdichten, von der Größenordnung 100 A/cm², um die es sich dabei handelt, bilden die nach *B* abfließenden Defektelektronen in den unmittelbar an *B* angrenzenden Schichten des Halbleiters eine positive Raumladung aus, die in der bekanntgewordenen Anordnung anscheinend noch dadurch verstärkt wird, daß in einer dünnen die obere Fläche des Halbleiters bedeckenden Schicht Defektelektronen abgebende Störstellen eingebaut sind, die im Betriebszustand weitgehend ihrer Defektelektronen beraubt sind (Erschöpfungsrandschicht) und infolgedessen die von *G* durch den Halbleiter nach *B* gelangenden Defektelektronen zu binden vermögen, so daß im Effekt die Defektelektronen zu längerem Aufenthalt im Randgebiet vor *B* gezwungen und somit in ihrer felderhöhenden Raumladungswirkung unterstützt werden.

In Erkenntnis dieser in der Literatur bisher nicht beschriebenen Wirkungsweise der an sich bekannten Anordnungen, in denen übrigens die Rolle der Überschuß- und Defektelektronen bei geeigneter anderer Wahl der Störstellen und evtl. des Grundmaterials sowie der Spannungen vertauscht werden kann, erscheint es als Idealziel, das Eindringen der Defektelektronen in die *B*-Elektrode, das deren Raumladungswirksamkeit gewissermaßen vorzeitig beendet, ganz zu vermeiden und die Defektelektronen so lange in der vor *B* wirksamen Raumladungskathodenschicht des Halbleiters verweilen zu lassen, bis sie durch Wiedervereinigung mit den diese Schicht passierenden Elektronen, ihr unvermeidliches und natürliches Ende finden. In dieser Richtung bieten sich im Rahmen der bekannten Anordnung gewisse Möglichkeiten, indem man die Defektelektronen abgebende Störstellenschicht vor der *B*-Elektrode genügend breit macht und die Ablösungsarbeit der Defektelektronen von ihren neutralen Störstellen genügend groß, so daß eine durch das starke Randfeld ihres Defektelektrons beraubte und dann durch ein aus dem Halbleiter kommendes Defektelektron wieder neutralisierte Störstelle ihre neutrale Ladung genügend lange behält, ehe sie durch thermische Anregung in Form eines abgespaltenen Defektelektrons wieder negativ aufgeladen wird.

Doch sind diesen Retardierungsmethoden der auf die *B*-Elektrode zuströmenden positiven Ladungsteilchen gewisse Schranken gesetzt. Erfindungsgemäß wird nun, alternativ oder in Kombination mit der Störstellenretardierung ein anderes Mittel angewandt, um die aus *G* kommenden Defektelektronen am Eindringen in die *B*-Elektrode zu verhindern und sie so lange in der vor *B* ausgebildeten Raumladungsrandschicht zurückzuhalten, bis sie durch Wiedervereinigung mit den aus *B* kommenden Überschußelektronen ihr natürliches Ende gefunden haben. Dieses Mittel besteht darin, daß man die Elektrode *B* nicht in direkte Berührung mit dem benutzten Halbleiter, der im folgenden als Grundkristall *Gr* bezeichnet wird, bringt, sondern zwischen Grundkristall und *B*-Elektrode eine vorzugsweise 10^{-5} bis 10^{-4} cm dicke Schicht eines anderen kristallinen Stoffes mit besonderen Eigenschaften, im folgenden als Fremdschicht *F* bezeichnet, zwischenschaltet.

Um die erfindungsgemäß verlangten Eigenschaften und die Wirkungsweise dieser Fremdschicht zu erläutern, sind in Fig. 1 die Energieniveaus für Überschuß- und Defektelektronen für zwei störstellenfreie, einander unmittelbar berührende verschiedenartige Kristalle dargestellt, wie sie gemäß der Erfindung für die Fremdschicht und den Grundkristall vorgeschrieben werden.

E_- bedeutet das Energieniveau, das ein überschüssig in den Kristall eingebrachtes Elektron im Ruhezustand einnehmen würde, E_+ das Energieniveau, das ein von außen eingebrachtes Elektron vorfindet, wenn es sich an den Ort einer ruhenden im Grundgitter des betreffenden Kristalls vorhandenen Elektronenlücke einbaut. (Im Rahmen der wellenmechanischen Vorstellungen bedeutet E_- den unteren Rand des tiefsten elektronenfreien Energiebandes, E_+ den oberen Rand des höchsten noch mit Elektronen voll besetzten Energiebandes). Der Niveauunterschied zwischen E_- und E_+ innerhalb jedes Kristalls bedeutet den Energieaufwand, um im ungestörten Kristall ein Elektron aus seinem normalen gebundenen Zustand in den freien beweglichen Zustand zu bringen, wobei gleichzeitig eine Elektronenlücke (Defektelektron) und ein Überschußelektron entsteht. Dieser Energieunterschied wird deshalb im folgenden als Elektronenpaarbildungsarbeit oder kurz als Paarbildungsarbeit bezeichnet. Die relative Lage von E_- bzw. E_+ in den beiden aneinandergrenzenden Kristallen kann, außer von den verschiedenen chemisch und strukturell bedingten Kräften, mit denen die Elektronen im E_- bzw. E_+ Niveau der beiden Kristalle gebunden sind, noch von etwaigen molekularen elektrischen Doppelschichten an der Kristallgrenze abhängen, ist aber bei reinen Substanzen und reinen Oberflächen sowie gegebenenfalls festgelegter Kristallorientierung eine eindeutige Eigenschaft der beiden Kristalle.

Erfindungsgemäß wird nun für den Grundkristall eine Substanz mit kleiner Paarbildungsarbeit gewählt, wie z. B. *Ge*, während die Fremdschicht eine mindestens um mehrere Zehntel *eV* größere Paarbildungsarbeit aufweisen soll, z. B. *Si*. Ferner soll E_+ im Grundkristall mindestens einige Zehntel *eV* oberhalb des E_+-Niveaus in der Fremdschicht liegen, während E_- im Grundkristall entweder unterhalb oder nur knapp oberhalb des E_--Niveaus in der Fremdschicht liegen soll. Da, wie durch die Pfeile in Fig. 1 angedeutet, die mit − bezeichneten Überschußelektronen jeweils das niedrigere Energieniveau zu erreichen streben, besteht unter den Verhältnissen von Fig. 1 keine Hemmung für den Übergang der Überschußelektronen aus der Fremdschicht in den Grundkristall. Dagegen bedeutet der Übergang einer Elektronenlücke, d. h. eines Defektelektrons +, von unten nach oben den Übergang eines Elektrons von oben nach unten;

Patentansprüche:

1. Halbleiteranordnung mit einem Halbleiterkristall, der mit zwei stromführenden Elektroden kontaktiert und außerdem mit einer Steuerelektrode versehen ist, welche den zwischen den beiden stromführenden Elektroden im Halbleiterkristall im wesentlichen parallel zur Fläche der Steuerelektrode fließenden elektrischen Strom kapazitiv steuert, **dadurch gekennzeichnet,** daß zwischen dem stromführenden Halbleiterkristall und der ebenfalls als Halbleiterkristall ausgebildeten Steuerelektrode eine elektronische Sperrschicht (Verarmungsrandschicht) erzeugt ist.

2. Halbleiteranordnung nach Anspruch 1, dadurch gekennzeichnet, daß die Kristallite der Halbleiterkörper so groß sind, daß eine etwaige weitere Auskristallisation den Widerstand des gesamten Halbleiters nicht mehr verändert.

3. Halbleiteranordnung nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß ein elektronenleitender Halbleiterkristall durch einen defektelektronenleitenden Halbleiterkristall gesteuert ist.

4. Halbleiteranordnung nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß ein defektelektronenleitender Halbleiterkristall durch einen elektronenleitenden Halbleiterkristall gesteuert ist.

5. Halbleiteranordnung nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß zusätzlich zu dem äußeren Feld der Steuerelektrode noch innere Felder vorgesehen sind, die von geordneten atomaren oder molekularen Schichten ausgehen.

6. Halbleiteranordnung nach einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß die Halbleiter aus Silicium oder Germanium bestehen.

7. Halbleiteranordnung nach einem der Ansprüche 1 bis 6, dadurch gekennzeichnet, daß die Halbleiter aus CU_2O, Se, PbS oder ZnS bestehen.

8. Halbleiteranordnung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß an der Steuerelektrode ein Spannungsabfall aufrechterhalten ist.

9. Halbleiteranordnung nach einem der Ansprüche 1 bis 8, dadurch gekennzeichnet, daß die Stromelektroden auf die Halbleiterkristalle sperrschichtfrei aufgebracht sind.

10. Halbleiteranordnung nach einem der Ansprüche 1 bis 9, dadurch gekennzeichnet, daß der stromführende Halbleiterkristall auf eine elektrisch isolierende Trägerplatte möglichst hoher Wärmeleitfähigkeit aufgebracht ist.

Bei Untersuchungen über die Wanderung von Farbzentren in einem Alkalihalogenidkristall, die von R. W. Pohl in den Nachr. von der Ges. d. Wiss. zu Göttingen, Jahresber. 1933/34, S. 55, beschrieben sind, ist der Gedanke geäußert worden, die Elektronenröhren in den Rundfunkgeräten durch kleine Kristalle zu ersetzen. Zu einem modellmäßigen Versuch über die Steuerung von Elektronen in Kristallen kam es jedoch erst mehrere Jahre später, als man die Bedeutung der Sperrschichten für die Gleichrichtung erkannt hatte. Es ist damals vorgeschlagen worden, in die Sperrschicht eines Alkalihalogenidkristalls ein Steuergitter einzubauen; vgl. hierzu R. Hilsch und R. W. Pohl, Z. S. Phys., 111, 399, 1938. Die Sperrschicht ist hier der glasklare, an eine Elektrode grenzende Teil des sonst mit Farbzentren erfüllten Kristalls. Sie ist bei diesen Versuchen von makroskopischen Abmessungen, und der zu steuernde Strom durchfließt dabei die Sperrschicht senkrecht, oder genauer gesagt, er fließt im wesentlichen parallel zur Dickenausdehnung der Sperrschicht. Im allgemeinen ist die Trägheit der mit Alkalihalogenidkristallen arbeitenden Anordnung ungeheuer groß, und ein stationärer Zustand stellt sich überhaupt nicht ein. Aus diesen Gründen haben die genannten Versuche nicht zu einem technisch brauchbaren Gleichrichter oder gar Verstärker geführt.

2

Ganz anders liegen die Verhältnisse bei den technischen Gleichrichtern (Selen- u. Kupferoxydulgleichrichter, Spitzendetektor). Die hier auftretenden Sperrschichten sind nicht wie die glasklaren Sperrschichten bei den Alkalihalogenidkristallen elektrisch neutral, sondern besitzen eine merkliche, mit der äußeren elektrischen Spannung veränderliche elektrische Raumladung. Zur Erläuterung des Sachverhaltes wird festgestellt, daß bei obigen Versuchen außer den beweglichen Elektronen (gewöhnliche Elektronen oder die neuerdings viel diskutierten Defektelektronen) gleichzeitig auch bewegliche Ionen vorhanden sind. Eine Sperrschicht entsteht in diesem Falle dadurch, daß sowohl die Elektronen als auch die Ionen aus dem fraglichen Gebiet herauswandern. Die Bewegung erfolgt so, daß nirgends ein Überschuß an Ladung auftritt; es treten daher auch keine rücktreibenden Kräfte auf; die Dicke der Sperrschicht kann daher unbegrenzt wachsen. Bei den technischen Gleichrichtern hingegen ist die Ionenbeweglichkeit vernachlässigbar klein. Das Herauswandern der Elektronen aus einem Randgebiet führt notwendig zur elektrischen Aufladung dieses Gebietes. Die dabei auftretenden rücktreibenden Kräfte verhindern, daß die Sperrschichten beliebig dick werden. Neuerdings, vergleiche hierzu W. Schottky: Über Sperrschichten, Schweizer Archiv, 1941, Heft 1 und 3, insbesondere S. 29 oben rechts und Anmerkung 13, hat man die Dicke dieser Sperrschichten, die wir zur Unterscheidung von den Sperrschichten bei Alkalihalogenidkristallen elektronische Sperrschichten nennen wollen, zu 10^{-5} cm abgeschätzt und auch aufgeklärt, weshalb gerade bei den technisch brauchbaren Kristallgleichrichtern der Einbau eines Steuergitters in die Sperrschicht und damit der Bau eines Kristallverstärkers auf rein elektronischer Grundlage unmöglich ist.

Heil beschreibt in der britischen Patentschrift 439 457 eine Anordnung, bei der die nach dem geschilderten Stand der Technik sich darbietenden Schwierigkeiten teilweise vermieden werden. Bei dieser bekannten Anordnung werden in Kristallen unter der Wirkung eines elektrischen Steuerfeldes elektronische Randschichten erzeugt und verändert, und der zu steuernde Strom wird senkrecht zur

CRYSTAL DEVICE FOR CONTROLLING ELECTRIC CURRENTS BY MEANS OF A SOLID SEMICONDUCTOR

Herbert François Mataré and Heinrich Welker, Vaucresson, France, assignors to Societe Anonyme dite: Compagnie des Freins et Signaux Westinghouse, Paris, France

Application August 11, 1949, Serial No. 109,752

Claims priority, application France
August 13, 1948

3 Claims. (Cl. 317—235)

1

This invention relates to crystal devices for controlling electric currents by means of a solid semiconductor with the use of one or more control electrodes, either in a barrier layer of the semiconductor (see for example patent of addition No. 38,744 of July 5, 1930, to French Patent No. 649,432 of January 28, 1928, and French Patent No. 866,372 of October 5, 1942), or closely adjacent to semiconductive layers with a suitable insulator interposed therebetween (see French Patent No. 786,454 of March 1, 1935).

However, such systems were so difficult to apply on a commercial scale that they had to be abandoned or development had to be restricted to simple experimental models or laboratory samples. This experience is supported by publications such as: Nachrichten der Gesellschaft der Wissenschaften zu Göttingen, Yearly Report, by R. W. Pohl, 1933/34, page 55; Schweizer Archive, 1941, volumes 1 and 3: Ueber Sperrschichten, by W. Schottky; Zeitschrift fur Physik, vol. 111, volumes 5 and 6, 1938 (R. Hilsch and R. W. Pohl); Modern Theory of Solids, 1940 (F. Seitz); Crystal Rectifiers, 1948 (H. C. Torrey and C. A. Whitmer).

In order practically to carry into effect systems comprising solid semiconductors arranged to produce electronic relay effects similar to those occurring in electronic tubes, two essential difficulties must be overcome. Firstly, the diameter of the contact area between metal needle and crystal should be of an order proportional to the thickness of the crystal barrier layer. Secondly, the gap between the conductive electrodes where engagement occurs with the semiconductor should be so selected that one of the conductive electrode point members will be positioned inside the barrier layer area of the other point member.

With the thickest barrier layer made hitherto, it would have been necessary to use values lower than 5 μ both for the diameters of the contact areas, on the one hand, and for the gap be-

2

or n-type excess and p-type deficiency concentration, respectively, that the inner resistivity of the device becomes very high. Arrangements of this type cannot be used practically for technical purposes.

The present invention permits to eliminate the above-mentioned difficulties and to realize on a commercial scale multi-electrode crystal devices of this kind for producing electronic relay action.

A more specific object of this invention is a multi-electrode device with at least two semiconductors of different conductivity characteristics; one of the semiconductors forms a control electrode and includes a surface barrier layer.

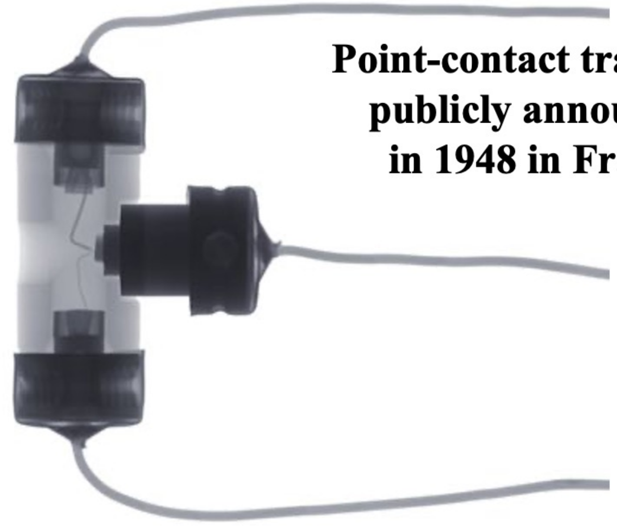
According to another feature of the invention, one of the semiconductors preferably the control electrode has a p-type (deficiency) or non-electronic conductivity and the other semiconductor an n-type (excess) or electronic conductivity.

According to a further feature of the invention, a semiconductor, preferably the other semiconductor mentioned above also includes a surface or internal barrier layer.

In one embodiment of the invention, the semiconductors or electrodes of the crystal are formed simultaneously from a single semiconductive element (such as germanium). In this element, by any suitable known method, zones of different conductivity characteristics are created.

Still in accordance with the invention, in at least one of said semiconductors or in one of the zones thereof such geometrical configuration is provided as to assure substantial radial distribution of the lines of force of the electric fields.

Furthermore, the invention relates to novel commercial products comprising multi-electrode crystal devices wherein external conductive electrodes are in direct contact with each semiconductive electrode, and wherein there is a gap between the contact points which is greater than 50 μ.



Point-contact transistor publicly announced in 1948 in France

Figure 6.86: Heinrich Welker and Herbert Mataré began developing a point-contact transistor in Germany during the war, filed a detailed patent application based on that wartime work on 6 April 1945, and publicly announced their transistor in 1948 in France.

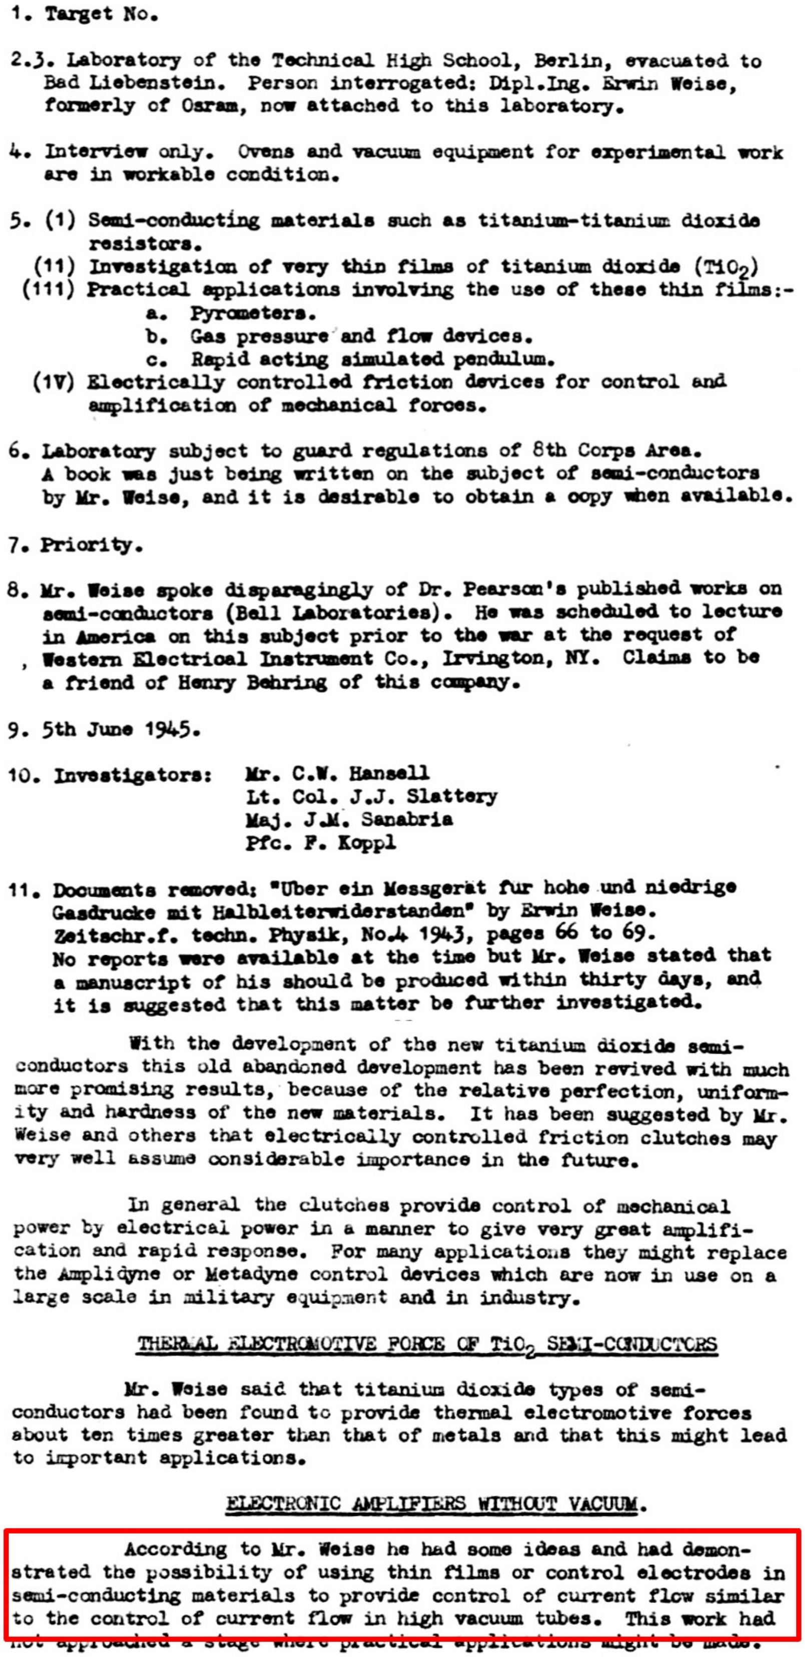
Erwin Weise (19??–19??) described a transistor to Allied investigators

CIOS XXXI-2



1. Target No.

2.3. Laboratory of the Technical High School, Berlin, evacuated to Bad Liebenstein. Person interrogated: Dipl.Ing. Erwin Weise, formerly of Osram, now attached to this laboratory.

4. Interview only. Ovens and vacuum equipment for experimental work are in workable condition.

5. (1) Semi-conducting materials such as titanium-titanium dioxide resistors.
(11) Investigation of very thin films of titanium dioxide (TiO_2)
(111) Practical applications involving the use of these thin films:-
  a. Pyrometers.
  b. Gas pressure and flow devices.
  c. Rapid acting simulated pendulum.
(1V) Electrically controlled friction devices for control and amplification of mechanical forces.

6. Laboratory subject to guard regulations of 8th Corps Area. A book was just being written on the subject of semi-conductors by Mr. Weise, and it is desirable to obtain a copy when available.

7. Priority.

8. Mr. Weise spoke disparagingly of Dr. Pearson's published works on semi-conductors (Bell Laboratories). He was scheduled to lecture in America on this subject prior to the war at the request of Western Electrical Instrument Co., Irvington, NY. Claims to be a friend of Henry Behring of this company.

9. 5th June 1945.

10. Investigators: Mr. C.W. Hansell
Lt. Col. J.J. Slattery
Maj. J.M. Sanabria
Pfc. F. Koppl

11. Documents removed: "Uber ein Messgerat fur hohe und niedrige Gasdrucke mit Halbleiterwiderstanden" by Erwin Weise. Zeitschr.f. techn. Physik, No.4 1943, pages 66 to 69. No reports were available at the time but Mr. Weise stated that a manuscript of his should be produced within thirty days, and it is suggested that this matter be further investigated.

With the development of the new titanium dioxide semi-conductors this old abandoned development has been revived with much more promising results, because of the relative perfection, uniformity and hardness of the new materials. It has been suggested by Mr. Weise and others that electrically controlled friction clutches may very well assume considerable importance in the future.

In general the clutches provide control of mechanical power by electrical power in a manner to give very great amplification and rapid response. For many applications they might replace the Amplidyne or Metadyne control devices which are now in use on a large scale in military equipment and in industry.

THERMAL ELECTROMOTIVE FORCE OF TiO_2 SEMI-CONDUCTORS

Mr. Weise said that titanium dioxide types of semi-conductors had been found to provide thermal electromotive forces about ten times greater than that of metals and that this might lead to important applications.

ELECTRONIC AMPLIFIERS WITHOUT VACUUM.

According to Mr. Weise he had some ideas and had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes. This work had not approached a stage where practical applications might be made.

Figure 6.87: Erwin Weise told Allied investigators that he "had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes" to create "electronic amplifiers without vacuum."

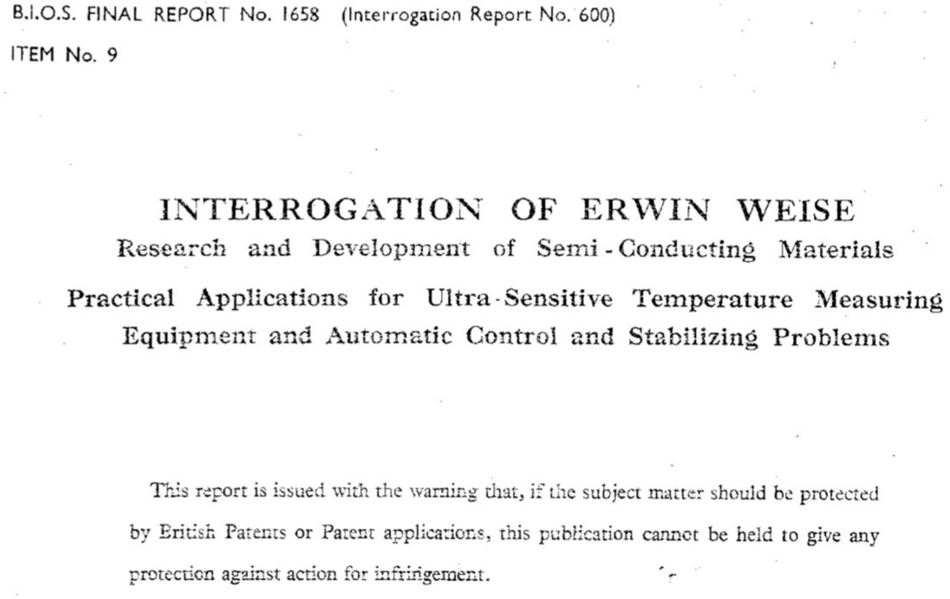
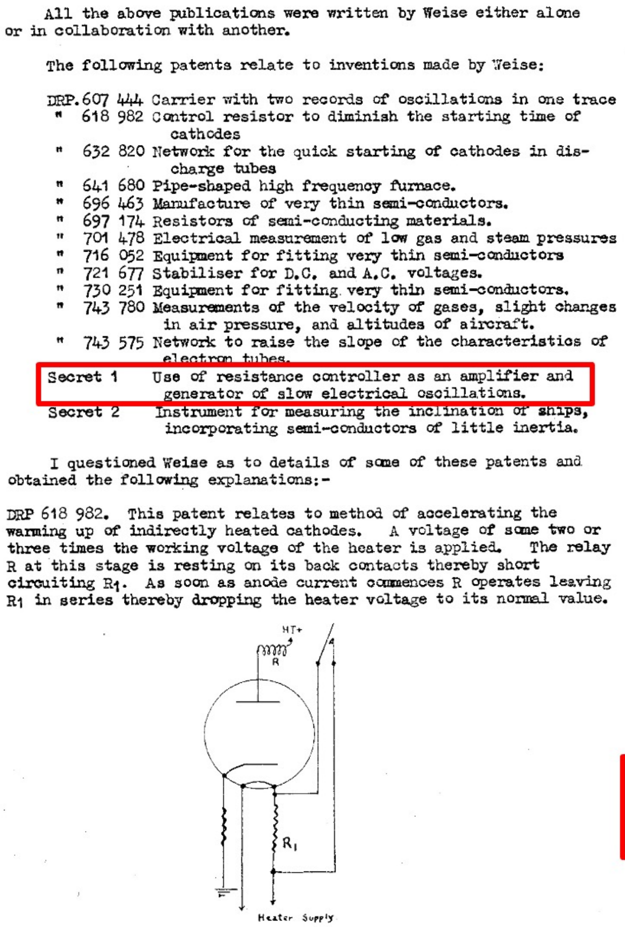
BIOS 1658



B.I.O.S. FINAL REPORT No. 1658 (Interrogation Report No. 600)
ITEM No. 9

INTERROGATION OF ERWIN WEISE
Research and Development of Semi-Conducting Materials
Practical Applications for Ultra-Sensitive Temperature Measuring
Equipment and Automatic Control and Stabilizing Problems

This report is issued with the warning that, if the subject matter should be protected by British Patents or Patent applications, this publication cannot be held to give any protection against action for infringement.



All the above publications were written by Weise either alone or in collaboration with another.

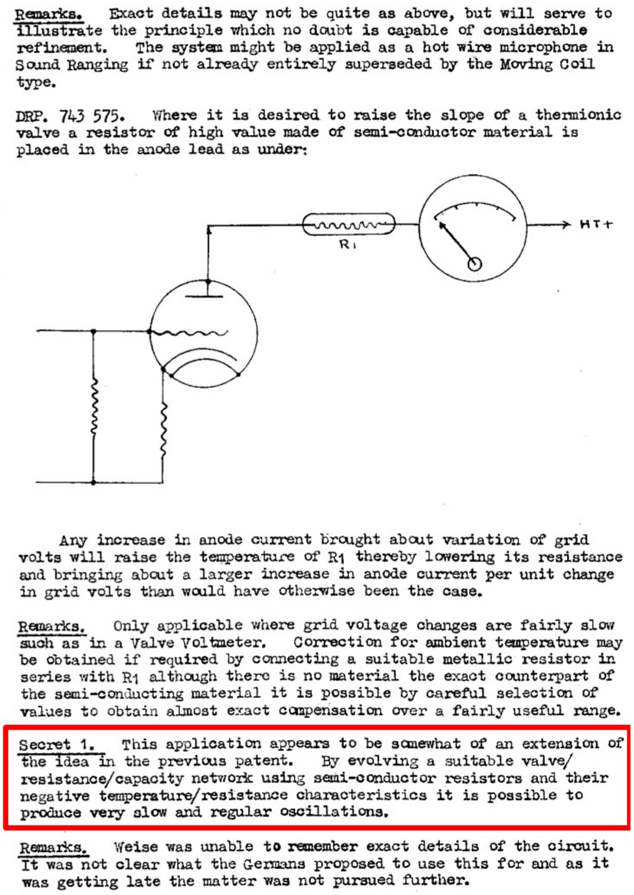
The following patents relate to inventions made by Weise:

DRP. 607 444 Carrier with two records of oscillations in one trace
" 618 982 Control resistor to diminish the starting time of cathodes
" 632 820 Network for the quick starting of cathodes in discharge tubes
" 641 680 Pipe-shaped high frequency furnace.
" 696 463 Manufacture of very thin semi-conductors.
" 697 174 Resistors of semi-conducting materials.
" 701 478 Electrical measurement of low gas and steam pressures
" 716 052 Equipment for fitting very thin semi-conductors
" 721 677 Stabiliser for D.C. and A.C. voltages.
" 730 251 Equipment for fitting very thin semi-conductors.
" 743 780 Measurements of the velocity of gases, slight changes in air pressure, and altitudes of aircraft.
" 743 575 Network to raise the slope of the characteristics of electron tubes.
Secret 1 Use of resistance controller as an amplifier and generator of slow electrical oscillations.
Secret 2 Instrument for measuring the inclination of ships, incorporating semi-conductors of little inertia.

I questioned Weise as to details of some of these patents and obtained the following explanations:-

DRP 618 982. This patent relates to method of accelerating the warming up of indirectly heated cathodes. A voltage of some two or three times the working voltage of the heater is applied. The relay R at this stage is resting on its back contacts thereby short circuiting R_1. As soon as anode current commences R operates leaving R_1 in series thereby dropping the heater voltage to its normal value.

HT+
R
R_1
Heater Supply



Remarks. Exact details may not be quite as above, but will serve to illustrate the principle which no doubt is capable of considerable refinement. The system might be applied as a hot wire microphone in Sound Ranging if not already entirely superseded by the Moving Coil type.

DRP. 743 575. Where it is desired to raise the slope of a thermionic valve a resistor of high value made of semi-conductor material is placed in the anode lead as under:

Any increase in anode current brought about variation of grid volts will raise the temperature of R_1 thereby lowering its resistance and bringing about a larger increase in anode current per unit change in grid volts than would have otherwise been the case.

Remarks. Only applicable where grid voltage changes are fairly slow such as in a Valve Voltmeter. Correction for ambient temperature may be obtained if required by connecting a suitable metallic resistor in series with R_1 although there is no material the exact counterpart of the semi-conducting material it is possible by careful selection of values to obtain almost exact compensation over a fairly useful range.

Secret 1. This application appears to be somewhat of an extension of the idea in the previous patent. By evolving a suitable valve/resistance/capacity network using semi-conductor resistors and their negative temperature/resistance characteristics it is possible to produce very slow and regular oscillations.

Remarks. Weise was unable to remember exact details of the circuit. It was not clear what the Germans proposed to use this for and as it was getting late the matter was not pursued further.

Figure 6.88: Erwin Weise told Allied investigators that he “had demonstrated the possibility of using thin films or control electrodes in semi-conducting materials to provide control of current flow similar to the control of current flow in high vacuum tubes” to create “electronic amplifiers without vacuum.”

Anordnung mit mindestens einem Widerstandselement, dessen Widerstand von wenigstens einer Steuerspannung abhängt.

Gegenstand der Erfindung ist eine Anordnung mit mindestens einem Widerstandselement, dessen Widerstand von wenigstens einer Steuerspannung abhängt.

Die Erfindung nützt jene Erscheinung aus, die man — insbesondere bei Halbleitern, wie z. B. Selen — als Sperrschichtbildung bezeichnet. Bei Halbleitern und bei verschiedenen andern Stoffen treten, wie seit langem bekannt ist, an denjenigen Stellen, die mit einem geeigneten Metall kontaktiert sind, sogenannte Sperrschichten auf, das heißt Schichten, die in ihrem Auftreten und in der Stärke von der Größe der angelegten Spannung abhängig sind und für den Stromdurchgang einen großen Widerstand bilden. Dieses Verhalten wird z. B. bei den sogenannten Trockengleichrichtern ausgenutzt, bei denen eine dünne Halbleiterschicht auf der einen Seite sperrfrei kontaktiert ist, während sie auf der andern Seite mit einer sperrschichtbildenden Belegung, der Sperrelektrode, versehen ist. Die Wirkungsweise solcher Gleichrichter ist bekanntlich die, daß sich bei Anlegung einer Spannung in der einen Richtung eine Sperrschicht ausbildet, die den Stromdurchgang in dieser Richtung praktisch sperrt, das heißt den Strom in dieser Richtung sehr klein sein läßt. Es ist nun beobachtet worden, daß die Dicke der sich ausbildenden Sperrschicht von der Größe der angelegten Spannung abhängig ist. Bei wachsender Spannung dehnt sich die Schicht hohen Widerstandes, das heißt die Sperrschicht, weiter in den Halbleiter oder den sonstigen, den Sperrschichteffekt aufweisenden Stoff hinein aus. Die von der Sperrschicht unberührt bleibende Schicht des Stoffes wird also um die Schichtstärke der Sperrschicht kleiner. Bei der Anordnung nach der vorliegenden Erfindung ist diese Erscheinung ausgenutzt; und zwar dadurch, daß erfindungsgemäß wenigstens ein Strompfad des Widerstandselementes in einem Halbleiter verläuft und von einer Sperrschicht eingegrenzt ist, die eine Blende für den Strom bildet, deren Öffnungsweite von der Steuerspannung abhängig ist (Sperrschichtblende).

Die Erfindung betrifft ferner ein Verfahren zur Herstellung einer besonderen Ausführungsform dieser Anordnung. Dieses Verfahren wird an Hand der Fig. 4 beispielsweise erläutert werden.

Es bestehen verschiedene Möglichkeiten für den Aufbau einer solchen Anordnung. Zum Beispiel kann der Widerstand aus einem mit zwei Anschlußelektroden versehenen Halbleiterkörper gebildet werden, während die in seinem Strompfad liegende Sperrschichtblende durch eine Stelle starker Zusammendrängung der Strombahnen und durch eine an dieser Stelle angebrachte Sperrelektrode gebildet wird. Diese Zusammendrängung der Strombahnen läßt sich durch entsprechende Formgebung des Halbleiterkörpers herbeifüh-

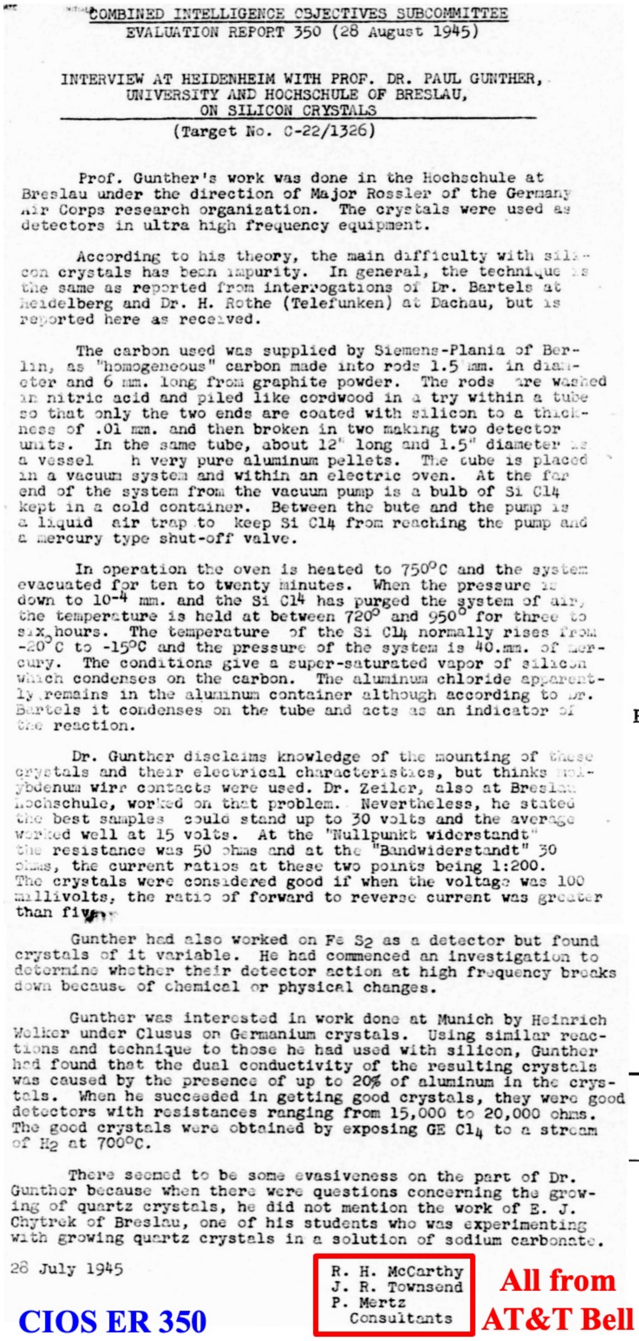
Design and fabrication of silicon semiconductor devices (wartime onward)



COMBINED INTELLIGENCE OBJECTIVES SUBCOMMITTEE
EVALUATION REPORT 350 (28 August 1945)

INTERVIEW AT HEIDENHEIM WITH PROF. DR. PAUL GUNTHER,
UNIVERSITY AND HOCHSCHULE OF BRESLAU,
ON SILICON CRYSTALS
(Target No. C-22/1326)

Prof. Gunther's work was done in the Hochschule at Breslau under the direction of Major Rossler of the Germany Air Corps research organization. The crystals were used as detectors in ultra high frequency equipment.

According to his theory, the main difficulty with silicon crystals has been impurity. In general, the technique is the same as reported from interrogations of Dr. Bartels at Heidelberg and Dr. H. Rothe (Telefunken) at Dachau, but is reported here as received.

The carbon used was supplied by Siemens-Plania of Berlin, as "homogeneous" carbon made into rods 1.5 mm. in diameter and 6 mm. long from graphite powder. The rods are washed in nitric acid and piled like cordwood in a try within a tube so that only the two ends are coated with silicon to a thickness of .01 mm. and then broken in two making two detector units. In the same tube, about 12" long and 1.5" diameter is a vessel h very pure aluminum pellets. The tube is placed in a vacuum system and within an electric oven. At the far end of the system from the vacuum pump is a bulb of Si Cl4 kept in a cold container. Between the bute and the pump is a liquid air trap to keep Si Cl4 from reaching the pump and a mercury type shut-off valve.

In operation the oven is heated to 750°C and the system evacuated for ten to twenty minutes. When the pressure is down to 10^{-4} mm. and the Si Cl^4 has purged the system of air, the temperature is held at between 720° and 950° for three to six hours. The temperature of the Si Cl4 normally rises from -20°C to -15°C and the pressure of the system is 40.mm. of mercury. The conditions give a super-saturated vapor of silicon which condenses on the carbon. The aluminum chloride apparently remains in the aluminum container although according to Dr. Bartels it condenses on the tube and acts as an indicator of the reaction.

Dr. Gunther disclaims knowledge of the mounting of these crystals and their electrical characteristics, but thinks molybdenum wirr contacts were used. Dr. Zeiler, also at Breslau Hochschule, worked on that problem. Nevertheless, he stated the best samples could stand up to 30 volts and the average worked well at 15 volts. At the "Nullpunkt widerstandt" the resistance was 50 ohms and at the "Bandwiderstandt" 30 ohms, the current ratios at these two points being 1:200. The crystals were considered good if when the voltage was 100 millivolts, the ratio of forward to reverse current was greater than five.

Gunther had also worked on Fe S_2 as a detector but found crystals of it variable. He had commenced an investigation to determine whether their detector action at high frequency breaks down because of chemical or physical changes.

Gunther was interested in work done at Munich by Heinrich Welker under Clusus on Germanium crystals. Using similar reactions and technique to those he had used with silicon, Gunther had found that the dual conductivity of the resulting crystals was caused by the presence of up to 20% of aluminum in the crystals. When he succeeded in getting good crystals, they were good detectors with resistances ranging from 15,000 to 20,000 ohms. The good crystals were obtained by exposing GE Cl_4 to a stream of H_2 at 700°C.

There seemed to be some evasiveness on the part of Dr. Gunther because when there were questions concerning the growing of quartz crystals, he did not mention the work of E. J. Chytrek of Breslau, one of his students who was experimenting with growing quartz crystals in a solution of sodium carbonate.

METHOD OF MAKING SURFACE-TYPE AND POINT-TYPE RECTIFIERS AND CRYSTAL-AMPLIFIER LAYERS FROM ELEMENTS

Karl Seiler, Nurnberg, Germany, assignor to International Standard Electric Corporation, New York, N. Y., a corporation of Delaware

Application April 5, 1950, Serial No. 154,064

Claims priority, application Germany April 6, 1949

4 Claims. (Cl. 117—106)

Unlike the large variety of point-type rectifiers (crystal diodes) there are only a few combinations of metals and semiconductors which exhibit a surface-type rectifying effect. Schottky's analysis of semiconductor rectification (see f. i. Zeitschrift für Physik, vol. 118, 1942, pp. 539–592) sets forth several reasons which may serve to clarify this fact.

(1) The relative impurity concentration throughout the semiconductor should be a minimum in the zone of increased resistance immediately adjacent the metallic electrode, in order to avoid short-circuits. Any increase in the number of impurities in this zone means great probability of short-circuits due to so-called by-passes.

(2) In the adjacent semi-conducting zone, however, adequate conductivity has to be provided by lattice-disturbing (impurity) atoms sufficient in number to greatly accentuate the zone mentioned in paragraph (1) where the so-called borderline effects take place.

To fulfil this requirement the disassociation level of the impurity atoms should be low (the impurity atoms should not diffuse readily), while the mobility of the electric carriers should be high. That only a few surface-type rectifications effects have been realized so far, derives from the fact that these two demands have not, or have hardly, been possible of fulfilment so far, for the known methods of making specified layer patterns are based exclusively on such processes where the space distribution of the impurities, is only obtained by modifications introduced by a secondary process by removing impurities at a suitable temperature, by chemical reaction (f. i. dissolving, lacquer-layers applied later on, etc.). Hence in making some specified layer pattern, the substances intended to produce the desired effects are placed at their respective locations in a first operation where no attention can be paid as to obtaining any specified space distribution of impurities, while that specified distribution, essential for proper performance, is brought about only subsequently in a second process governed by laws different from those of the first one. Thus one has been forced to simply accept as given whatever impurity concentration and distribution resulted from that second process without the possibility of introducing such corrective action of one's own as might be desirable to secure optimum distribution of impurities across the layer. With regard to the fact that very delicate arrangements are involved with layers present only as extremely thin films, it is obvious that the probability of inadequate results is rather large if these two essential processes are practiced one after the other.

In rectifiers involving compound-type semiconductors (in particular cuprous oxide) this fact is particularly pronounced as here the change in impurity concentration is caused by a chemical reaction which in turn is to introduce the stoichiometric unbalance of the semiconductor compound.

Generally a high impurity concentration is provided in the zones of the semiconductor more remote from the metallic electrode. But a certain maximum impurity concentration should not be exceeded in the zone of the semiconductor immediately adjacent the metallic electrode. This means that along the main direction of current flow the impurity concentration will have to obey a specified functional law, i. e. the dependence of the impurity concentration at a particular layer level will depend on the distance between that layer and the metallic

2

electrode. This distance, however, is extremely small so it is obvious that rather erratic results are liable to occur in the few processes available for controlling the impurity concentration.

The drawbacks of the known methods are avoided in this invention by providing that the ultimate structure of the layer pattern is no longer obtained from two independent individual processes, but that the basic and the impurity substances are deposited simultaneously on the provided foundation, and that the specified relative impurity concentration is controlled to fit the needs of each particular layer while the layer is being built, so the desired space distribution of impurities is brought about.

It is known that the elements boron, silicon, germanium, and tellurium have semiconducting properties. In view of the delicacy of the processes to be controlled, the degree of chemical purity of the substances coated on the foundation electrode is of outstanding importance in making rectifiers.

In order to achieve uniform results and to control the porportion of the impurity admixture, it might seem desirable to vaporize the semiconductor materials and the impurity substances and deposit them from the vaporous state onto a suitable foundation. However, due to the high vaporizing temperatures of the materials involved there is induced the hazards of chemical reactions of the basic material or even the impurity contents with the material of the crucible which would produce uncontrolled and undesirable effects on the rectifying properties.

In order to avoid such high temperatures in production, one starts out in the known way from a liquid compound of the elements involved which by chemical rectification and customary chemical purifying methods can be prepared with a very high degree of purity and which in turn may be reduced chemically under proper conditions upon reaction with some equally pure reducing agent. Simultaneously with this reduction, the impurity substance may be treated in the same manner. With the relatively ample choice present in selecting admixtures to semiconducting elements, there is usually found some suitable chemical reaction mechanism which enables simultaneously synthesizing the impurity admixture. In a functional schematic, the nature of the process to be adopted is indicated in Fig. 1. A, B, C, and D refer schematically to devices where the substances needed for assembling the rectifying layer are obtained in their purest form by available processes according to what has been described above. As indicated schematically, these substances are then fed through pipes L_a, L_b, L_c, and L_d to the device E where the layer pattern is formed. In Fig. 1, these pipes L_a and L_b directly feed the device E with no prior intermixing of the substances being possible. Of course, one, two, or even all of the pipes could be joined in a common duct whenever intermixing of the substances is desired or permissible at such a relatively early stage of the production process. Equally in a schematic manner are shown control mechanisms R_a, R_b, R_c, and R_d at some arbitrary point along the ducts which allow any desired decrease or increase in the feeding rate of any of the ingredients while the semiconducting system is being built up. It is by no means essential that these controlling devices be inserted somewhere between the units A and E, B and E, etc., these controlling facilities may as well be incorporated straight in the units A, B, C, D or any additional units that might be present. Care will have to be taken, however, to prevent undesired reactions on the other devices B, C, D whenever at the junction of the pipes or individual pipe ducts the gas or vapor rate of device A is increased.

To practice this method, the elements boron, silicon, germanium, or tellurium may be used because of the high mobility of their electric carriers. To provide optimum efficiency, the impurity concentration at the back or counterelectrode is chosen large enough to prevent virtually any barrier layer from forming there.

As an example of the preparation of the semiconducting substance in building of a layer pattern, silicon may be reduced with hydrogen from silicon, tetrachloride or with zinc, in order to obtain pure silicon.

It is also known that the elements which are left and

COMPOSITE ELECTRODES FOR DIRECTIONAL CRYSTAL DEVICES

Paul Günther and Franz Kerkhoff, Munich, Germany, assignors to Siemens & Halske Aktiengesellschaft, Munich, Germany, a corporation of Germany

Application February 1, 1954, Serial No. 407,196

Claims priority, application Germany February 27, 1953

11 Claims. (Cl. 317—235)

This invention is concerned with composite electrodes for directional devices comprising semi-conductors, for example, transistors and the like.

Composite electrodes for the purpose and of the type noted above are generally known. It is likewise known to form on such electrodes preferably point-shaped or knife-edge contacts of a hard core which is provided with a coating of another generally softer material, the latter being more suitable than the core material to form electrical contact engagement with a semi-conductor crystal. Such a known electrode may, for example comprise a tungsten wire plated with platinum. The drawback of such structure is that it is impossible to provide upon tungsten a sufficiently uniform platinum coating and that it is consequently impossible to produce such electrodes with the required uniformity in the course of customary mass production processes.

It has been found by research lying in back of the invention that the above mentioned drawbacks can be avoided by using other particular materials. In accordance with the invention, electrodes of the previously indicated type which comprise at least two different materials, for example, a core or carrier and a coating, are made of metals from the first, fourth, fifth and/or eight groups of the periodic table of elements. More specifically a hard material as for example niobium, tantalum, iron or alloys of such materials, for example, hard bronze of the type of phosphor-beryllium-bronze or the like may be used primarily for the core of the electrode; and for the coating may be used primarily materials of high output capacity, for example, rhodium, palladium, iridium, also platinum or, under some circumstances alloys of these materials. In the case of using in a transistor a plurality of electrodes, for example, two or three electrodes, the selection of the material for the surface coating will depend upon whether the electrode is to be employed as a collector or an emitter.

The invention will now be described with reference to the accompanying drawings showing in diagrammatic representation examples thereof. In these drawings,

Fig. 1 shows a germanium crystal coacting with a single point contact electrode; and

Fig. 2 illustrates a transistor comprising a germanium crystal coacting with two point contact electrodes.

In Fig. 1, numeral **1** indicates the germanium crystal. In contact engagement with the surface of the crystal is a point electrode comprising a wire **2** of phosphor-beryllium-bronze provided with a platinum coating **3**. The electrode is produced by providing upon the bronze wire, for example, in an alkaline ammonia phosphorous platinum bath of platinum coating in galvanic manner.

Fig. 2 shows a transistor comprising a germanium crystal **4** coacting with two point contact electrodes **5**

2

and **6**. Between the electrodes, a p-n layer is provided in a known manner. The electrode **5** is made like the electrode of Fig. 1, comprising a bronze core with a platinum coating **3**. The other electrode **6** comprises a steel core **7** covered by a copper coating **8**.

The coatings may be applied or provided in different manner than galvanic, for example, by vaporization, by cathode vaporization, or in mechanical manner, for example, by spraying or rolling. Burning such as is usually applied in the production of mirrors, ceramics, etc., is recommended for mass production.

What is believed to be new and desired to have protected is defined in the appended claims.

We claim:

1. A transistor comprising a crystal, in electrode in point contact with said crystal, said electrode including a core and a coating surrounding said core, said core formed from one or more metals of the group consisting of niobium, tantalum, iron, copper, tin, zinc, phosphorous, beryllium and alloys of the aforesaid metals, said coating formed from one or more metals of the group consisting of rhodium, palladium, iridium, platinum and alloys of the aforesaid metals, and said coating of said electrode in point contact with said crystal.

2. A transistor according to claim 1, wherein said core of the electrode comprises a hard bronze of the type of phosphor-beryllium-bronze.

3. A transistor according to claim 1, wherein said core of the electrode is formed of a hard bronze of the type of phosphor-beryllium-bronze, and said coating is formed of platinum.

4. A transistor comprising a crystal, at least two electrodes in point contact with said crystal, p-n layer provided in said crystal between the electrodes, one of said electrodes comprising a phosphor-beryllium-bronze core and a platinum coating, the other of said electrodes comprising a steel core and a copper coating, and said coatings of said electrodes in point contact with said crystal.

5. A composite electrode for a directional crystal device, said electrode provided with a point at one end for point contact with a crystal and comprising a core and a coating surrounding said core, said core formed from one or more materials of the group consisting of tantalum, phosphor-beryllium-bronze and steel, said coating formed from one or more materials of the group consisting of the elements of group eight of the periodic table of elements and consisting of rhodium, palladium, iridium and platinum.

6. A composite electrode according to claim 5, wherein said composite electrode may be used in a diode.

7. A composite electrode according to claim 5, wherein said composite electrode may be used as an emitter in a transistor.

8. A composite electrode for a directional crystal device said electrode formed with a point at one end for point contact with a crystal and comprising a steel core and a copper coating surrounding said core.

9. A composite electrode for use as a collector, said electrode comprising a core and a coating surrounding said core, said core formed from one or more materials of the group consisting of tantalum, phosphor-beryllium-bronze and steel, and said coating comprising one or more materials of the group consisting of copper and tin.

10. A semi-conductor device of the transistor type including a directional crystal, a composite electrode for point contact with said directional crystal, said composite electrode comprising a phosphor beryllium-bronze

Transistors (11) Helmar Frank and Jan Tauc

Bo Lojek. 2007. *History of Semiconductor Engineering.* pp. 195-204.

German military research maintained two research groups working on semiconductors in occupied Czechoslovakian "Böhmen und Mähren" territory: The Prague group headed by Prof. B. Gudden worked on the rectifying diode; a second and larger group worked in the small town of Tanvald in the North of Bohemia on microwave point contact diode and radar research. Many members of the German research groups, including Prof. Gudden, were killed in May 1945 during the liberation of Czechoslovakia by the Red Army. A major part of the Tanvald research facility was confiscated by the Soviet army and transferred to the Soviet Union; the rest of the inventory was set on fire and destroyed. Several kilograms of Germanium survived the fire and were used by Jan Tauc and Helmar Frank to build the first European [Czech] transistors in 1949. Jan Tauc later immigrated to the United States. Helmar Frank, who was also a student of Prof. Gudden at Charles University, directed post-war semiconductor research sponsored by the Czechoslovakian Army at the former Philips Laboratories in Prague. [...] At the end of the war, the CIA and KGB quickly joined the British effort and transferred several researchers from the Prague and Tanvald research groups to their respective countries.

Czech National Library of Technology. Professor Helmar Frank.
https://www.techlib.cz/cs/84002-profesor-helmar-frank

Helmar Frank was a Czechoslovak physicist of German nationality. […] He created the first Czechoslovak semiconductor amplifying component---the point-contact germanium transistor---and developed, initiated and helped to introduce production of semiconductor materials and components in many Czechoslovak factories.

National Academy of Sciences. 2011. *Jan Tauc 1922-2010.*
http://nas.nasonline.org/site/DocServer/Tauc_Jan.pdf

Jan's first job after graduation was at a government-supported research institute with a mission to develop electronic technologies (such as television and microwaves), using equipment and documentation left behind by the German army and declassified information from the West that became available after the war. The institute was located first in Tanvald, a mountainous region of northern Bohemia, which was the location of the former German army center. There Jan became involved in microwave detectors that the Germans had developed for the 10 cm wavelength band, using germanium. When the news of the invention of the transistor reached Prague, he used the germanium of those detectors to build the first point-contact transistor in Czechoslovakia and decided to stay in that field.

Figure 6.94: Helmar Frank and Jan Tauc produced transistors at the former German electronics laboratory in Tannwald/Tanvald in Czechoslovakia in 1949, based at least in part (and perhaps entirely) on wartime German work there.

TRANSISTOR POINT CONTACT ARRANGEMENT

Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts

Application December 31, 1952, Serial No. 328,948

6 Claims. (Cl. 317—235)

The present invention relates to new and improved point contact constructions for transistors.

The field of transistors is now so well known that it is not deemed necessary to devote any of the present specification to purely descriptive matter relating to this subject. In this connection, reference is made to the text "Holes and electrons in semiconductors" by Schockley, the entire November 1952 issue of the Proceedings of the Institute of Radio Engineers, as well as other publications.

One type of transistor which presently shows a great deal of promise requires the use of two point contacts termed the emitter and the collector bearing against a single crystal of a metal such as germanium, silicon, or other related semiconducting materials. A third low resistance electrical connection is made to such a crystal. In order to obtain satisfactory operating characteristics with this type of construction the two point contacts must be positioned relatively close, and must remain in a comparatively fixed position.

It is now a common procedure to hold these point contacts or probes in place by the use of a small amount of tension and a stiff gel-like filler material. Other means for accomplishing the same result have been suggested. These include the use of stiff fabric-like inserts through which the probes are inserted; the use of an adjacent wall upon which the point contacts are mounted; and other means. The number of suggestions made on the subject of positioning wire probes in itself indicates the ineffectiveness of the presently used procedures.

An object of the present invention is to improve upon the aforegoing and related methods for positioning wire point contacts against a body of a semiconducting material used in a transistor. A further object is to produce new and improved transistor constructions. These and other aims of the invention, as well as the advantages of it will be apparent from the following description and claims, as well as the accompanying drawings in which:

Figure 1 diagrammatically illustrates a transistor formed in accordance with this disclosure; and

Figure 2 is a diagrammatic view of a modified construction of the invention; and

Figure 3 is a diagrammatic view of a still further modified construction. In all figures like numerals designate like parts.

In Figure 1 of the drawings a simple transistor construction is shown in which a small semiconducting wafer **11** such as, for example, a germanium crystal about 30 x 50 x 150 mils in size is provided with two apertures **12** through which wire probes **14** project. Each of these probes **14** is insulated from the wafer **11** by an insulating sleeve **13** of polyethylene or the like, and is bent so that the point contacts **15** touch the same face of the crystal quite close to one another. Preferably a space of from 1 to 5 mils separates them. A low resistance contact **16** of known type is made to the wafer **11** through the wire **17**.

The modification shown in Figure 2 of the drawing

2

differs from the construction of Figure 1 solely in that the adjacent point contacts **15** are positioned upon opposite sides of a wall **21** in small cavities **22** formed within the wafer **11**. Preferably, this wall **21** should be from about 1 to about 5 mils thick. The construction shown in this figure has the advantage that with it the point contacts are not apt to be dislodged due to handling, as when encasing the entire unit in a protective insulating resin.

The same advantage is derived from the construction illustrated in Figure 3. Here the wire probes **14** are inserted through the holes **12** in the wafer **11** from opposite directions so that the point contacts **15** project towards one another within the cavities **32**, but are separated by the wall **31** which is preferably of the thickness previously indicated.

The various apertures and holes or cavities herein indicated can be found in a variety of methods known to the art, such as, for example, by the use of dental abrasive equipment.

The herein described invention has a number of advantages. Perhaps one of the most important of these is comparative ease with which it adapts itself to large scale production techniques. By one procedure a comparatively large flat body of a semiconductor can be provided with the apertures, holes, and/or cavities for a large number of transistors at the same time, the appropriate connections and probes indicated can be placed in position, and then the individual transistors actually formed by cutting the larger body. If desired, the initial block can be scored or perforated so as to assist in separating the individual units. Various known steps, not specifically indicated herein, such as, for example, etching can be carried out at any convenient stage in forming the units of the invention. Also, a construction similar to that shown in Figure 1 can be formed utilizing a very thin wafer with the point contacts positioned upon opposite sides of it in the broad manner indicated.

As many apparently widely different embodiments of this invention may be made without departing from the spirit and scope hereof, it is to be understood that the invention is not limited to the specific embodiments hereof except as defined in the appended claims.

What is claimed is:

1. A transistor comprising a body of a semiconducting material, means defining at least two closely-spaced apertures through said body, wire probe means passing through said apertures, insulating means separating said wire means from said body in said apertures, point contact means formed on the tips of said probe means, said point contact means forming rectifying contacts with parts of said body about 1 to 5 mils apart.

2. A transistor as defined in claim 1 wherein said contacts are both on the same face of said body.

3. A transistor comprising a body of a semiconducting material, means defining at least two closely-spaced apertures in said body, wire probe means passing through said apertures, insulating means separating said wire means from said body in said apertures, point contact means formed on the tips of said probe means and positioned within cavities upon the same face of said body, said point contact means forming rectifying contacts with adjacent parts of said body.

4. A transistor comprising a body of a semiconducting material, means defining at least two closely-spaced apertures in said body, wire probe means passing through said apertures, insulating means separating said wire means from said body in said apertures, point contact means formed on the tips of said probe means positioned upon opposed sides of said body, said point contact means forming rectifying contacts with adjacent parts of said body.

Figure 6.96: During the war, Bernhard Gudden and Kurt Lehovec ran a very secretive and well-funded group that was developing advanced semiconductor devices at Charles University in Prague. After the war, Gudden died in a Czech prison and Lehovec moved to the United States, where he filed patent applications on transistor designs, possibly based on the wartime work.

6.5.4 Postwar Transfer of Microelectronics Technologies

Appendix B presents evidence that suggests (but does not yet prove—much more investigation is required) that the German-speaking scientists' transistor developments not only preceded those of Bell Laboratories, but may have been directly used by Bell Laboratories as a guide to reproduce the earlier German-speaking work:

- The German-speaking transistor developments came from at least 12 different groups doing extensive work during a period of over two decades collectively.

- During World War II, the German military was keenly interested in funding the development of smaller, more rugged, and more sophisticated electronic guidance systems that could be used in rockets ranging from anti-aircraft missiles to intercontinental ballistic missiles. Transistors derived from the existing German patents and papers would have been an important part of those guidance systems.

- In spring 1945, hundreds of thousands of tons of German-language technical documents were seized by the United States, thousands of German-speaking scientists were interrogated by U.S. scientists and engineers, and countless prototypes, pieces of equipment, and whole laboratories were shipped to the United States.

- Personnel from Bell Laboratories played a prominent role in collecting that scientific information from Europe and processing it in the United States (for examples, see pp. 1078–1079 and Section B.5).

- In late 1945, Bell Laboratories put John Bardeen and Walter Brattain to work to try to produce a simple transistor, with some supervision by William Shockley. As noted by one source (p. 3015), "the semiconductor group at Bell Laboratories began its work with a survey of wartime developments in the field of semiconductors" [Eckert and Schubert 1990, p. 159].

- Bardeen and Shockley conducted detailed visits to numerous European laboratories from June through August 1947. During that time, Bardeen or Shockley could have easily encountered scientists, reports, or information from the earlier transistor development programs of the German-speaking world, or at least Allied investigators who had already studied those programs. Although any transistor-related information that Bardeen and Shockley learned during this time has never been publicly disclosed, Bardeen wrote at the end of the trip: "learned a lot during the trip, and have picked up some information that may be useful to the Lab" [Hoddeson and Daitch 2002, p. 130].

- Bardeen and Brattain did not begin serious experimentation with transistor-like devices until November 1947, two and a half years after the end of the war (and over two and a half years after the collection and study of German microelectronics information began in earnest). Within just a couple of months this very small team created what appears to be a crude replica of the earlier German work.

- Not only did Shockley not give any credit to the earlier German work, but he refused to give proper credit to Bardeen and Brattain, who actually performed the Bell Laboratories experiments.

- Due to their personal differences, the team of Bardeen, Brattain, and Shockley soon split up. Even in 1951, Western Electric (the manufacturing arm of AT&T/Bell Laboratories) was

> unable to produce reliable transistors. Most transistor development in the United States was carried out by other researchers, including several German-speaking scientists (Kurt Lehovec, Herbert Kroemer, Jean Hoerni, Eugene Kleiner, Karl Heinz Zaininger, etc.).

Much more archival research is needed to determine the true extent of microelectronics innovations in the German-speaking world, as well as how much that influenced postwar work in other countries.

Figures 6.99–6.100 show examples of how detailed technical information on the German semiconductor and microelectronics technologies was transferred to Allied countries after World War II. For instance, BIOS Final Report 725, *German Research on Rectifiers and Semi-Conductors*, described how German groups were making wafers of monocrystalline pure silicon, doping semiconductor materials with impurities to create the desired electrical properties, and producing semiconductor devices both from silicon and from germanium [BIOS 725]:

> Impurities in a semi-conductor produce additional energy-levels; perhaps a pure material could not be a semi-conductor. There must be some broadening of the energy levels into bands... Joos tried to produce large crystals of silicon for use in silicon-carbon detectors for cm. waves. The method was deposition from a solution of silicon in molten aluminum. The crystals so obtained were spectroscopically pure... They were aggregations of thin plates... Prof. Pohl confirmed that Dr. König had studied germanium and silicon rectifiers at Göttingen...

After the war, Hans K. Ziegler (German, 1911–1999) came to the United States in Operation Paperclip. He became the Chief Scientist of a U.S. Army laboratory in Fort Monmouth, New Jersey, that employed many other German-speaking scientists and harnessed many microelectronics technologies acquired from Germany, Austria, and Czech territory [Fort Monmouth Historical Office 2008]. See pp. 1153–1154, 2760, and 3013. Many other German-speaking scientists were hired by other U.S. laboratories or companies.

6.5.5 Capacitors

In addition to diodes and transistors, creators from the German-speaking world invented and perfected capacitors (sometimes called condensers), which temporarily store electric charge.

Ewald Georg von Kleist (German states, 1700–1748) invented and demonstrated the first capacitors in 1745; see Fig. 6.101. Pieter van Musschenbroek (Netherlands, 1692–1761) conducted further experiments with capacitors, and they became known as “Leiden jars.” Daniel Gralath (Danzig, 1708–1767) realized that multiple Leiden jars could be connected together to store more electric charge.

As shown in Fig. 6.102, Karol (Charles) Pollak (Polish, educated in Germany, worked in Germany and Austria, 1859–1928) invented the electrolytic capacitor in 1896. He also developed improved batteries and a variety of other electrical innovations.

Julius Edgar Lilienfeld invented and patented an improved design for electrolytic capacitors in 1931 (p. 1084).

In the 1930s, Eberhard Traub (German, 1906–20??) invented metallized paper capacitors, which worked well and could be manufactured very inexpensively. See Fig. 6.104.

The United States acquired Traub’s metallized paper capacitor technology in 1945, as illustrated in Figs. 6.105–6.106. Traub’s approach soon spread worldwide.

MR. EDWIN Y. WEBB, JR., Chief of
Electronics and Communication Unit
Office of Technical Services
Department of Commerce
Washington 25, D. C.

Dear Mr. Webb:

For your kind reception a couple of weeks ago I do wish to thank you before it is lost to memory.

Some of the German devices you are exhibiting are ingenious and represent advanced technique. I am conscious of having been technically stimulated by what I saw. It is always difficult to evaluate the effect of an exposure of this kind so subtle is our inspiration and our mode of thought, but the influence cannot help but be beneficial. It is apparent that in calling these developments to the attention of American Industry you are doing a real service, and I for one wish to express my appreciation.

I have just about gouged out my eyes trying to scan down and select the more interesting items in the succession of issues of the "Bibliography of Scientific and Industrial Reports". Doubtless the subject index of these items now being prepared will be a real help in this matter of selection. I am looking forward to studying more fully some of the reports that will be obtained in full by Mr. Blanchard.

With personal best wishes,

Sincerely,

/s/ Lloyd Espenschied

Dear Mr. Green:

You will be interested to know that the Laboratories has acquired a considerable amount of valuable information as a result of its contacts with the Office of Technical Services which were instituted last summer. This is in no small measure due to the friendly and cooperative attitude which we have encountered in our relations with your Office and for which we are most appreciative.

We plan to continue sending Dr. Blanchard to Washington, as a representative of the Western Electric Company as well as the Laboratories, where he will keep in touch with the literature that is coming from abroad as well as from various sources in this country. He has found the Office of Technical Services very helpful in his search for reports on subjects which are of special interest to the Western Electric Company and to the Laboratories.

It appears to us that your organization is proceeding most competently with the accomplishment of its objectives and we wish you further success in this program which is of such significance to American industry.

Very truly yours,

/s/ O. E. Buckley
President

Elektrischer Flüssigkeitskondensator mit Aluminiumelektroden.

Patentirt im Deutschen Reiche vom 14. Januar 1896 ab.

Der Gegenstand der vorliegenden Erfindung ist eine Verbesserung der als elektrostatische Kondensatoren verwendeten Zersetzungszellen, welche bezweckt, die Leistungsfähigkeit und Dauerhaftigkeit dieser Kondensatoren zu erhöhen und dieselben dadurch technisch brauchbar zu machen.

Die Möglichkeit der Verwendung elektrolytischer Zellen als Kondensatoren von groſser Capacität wurde bereits mehrmals hervorgehoben und bei wissenschaftlichen Experimenten in kleinem Maſsstabe auch durchgeführt, wobei pro Zelle bezw. Elektrodenpaar Spannungsunterschiede bis zu 5,5 Volt beobachtet wurden. (Wiedemann, Lehre von der Elektricität, 2. Auflage, Band 2, S. 757.)

Bei der technischen Anwendung solcher Zellen stieſs man jedoch auf eine Reihe bedeutender Schwierigkeiten, namentlich auf die geringe zulässige Spannung an den Elektroden, groſse Stromverluste wegen unvollkommener Isolation und geringe Ausdauer der Zellen.

In den englischen Patentschriften Nr. 7509 und 14189 vom Jahre 1892 sind Vorschläge zur gewerblichen Verwerthung derartiger Kondensatoren enthalten, jedoch ohne Angabe der Mittel und Zusammenstellungen, welche dies ermöglichen sollen.

Den Ausgangspunkt zu der vorliegenden Erfindung bildet die im Jahre 1875 von Ducretet beschriebene Entdeckung, daſs das Aluminium als positive Elektrode einer Zelle mit angesäuertem Wasser als Elektrolyt sich mit einer isolirenden Schicht umgiebt und dem Durchgange des Stromes in dieser Richtung einen groſsen Widerstand entgegensetzt. Er beabsichtigte, diese Eigenschaft des Aluminiums zur Construction flüssiger Stromunterbrecher zu benutzen.

Wie die Erfahrung gezeigt hatte, war auch diese Ausführungsform noch nicht technisch verwerthbar, da die sich auf dem Aluminium in saurer Lösung bildende Schicht zu unbeständig ist und nach einiger Zeit von der Platte abblättert. Auch ist die bei einem Kondensator unbedingt erforderliche gute Isolation der Platte von der Flüssigkeit auf diesem Wege nicht zu erreichen. Der Erfinder hat die Beobachtung gemacht, daſs bei der von Ducretet angegebenen Zusammenstellung selbst mäſsige Spannungen von etwa 20 Volt nicht genügend gut durch die Isolir- bezw. Polarisationsschicht aufgehalten werden können. Die Technik braucht aber meistens nur Kondensatoren, die bei mindestens 65 oder 110 Volt arbeiten können.

Die gegenwärtige Erfindung ermöglicht nun die Herstellung einer vollkommen isolirenden Polarisationsschicht auf Aluminiumplatten durch entsprechende Wahl des Elektrolyten und Vorbereitung der Platten.

Die sich dabei auf dem Metalle bildende Schicht kann als Dielektricum eines Kondensators verwendet werden. Statt der sauren Lösung, wie bei Ducretet, nimmt man hierzu alkalische oder neutrale Lösungen, wie z. B. die neutralen Salze des Aluminiums, des Eisens, des Chroms u. s. w. Eine Ausführung der Erfindung wird an nachfolgendem Beispiel erläutert.

Eine Zelle mit alkalischer Lösung als Elektrolyt und zwei Aluminiumplatten als Elektroden

Charles POLLAK, in FRANKFURT a/M. (Deutschland).

Akkumulatorplatte.

Der Gegenstand der Erfindung ist eine Akkumulatorplatte von großer Festigkeit und Dauerhaftigkeit, bei welcher sich der stromleitende Kern mit der porösen Oberfläche in innigster metallischer Verbindung befindet, wobei die poröse Schicht aus einer Fortsetzung und Verzweigung des Kernes selbst besteht.

Die Gestalt des massiven Kernes ist eine beliebige, die Beschaffenheit des porösen Teiles eine feinkörnige, um eine möglichst große, wirksame Oberfläche der Platte zu erhalten.

In Fig. 1 ist der Querschnitt einer solchen porösen Kernplatte in stark vergrößertem Maßstabe dargestellt. *a* bezeichnet den massiven Kern, *b* den porösen Teil der Platte. Der Kern *a* geht ohne jede Unterbrechung in die Verzweigungen *d* über, zwischen denen sich Öffnungen und Kanäle *c* befinden, welche dem Elektrolyt freien Zutritt gewähren.

Die Fig. 2, 3, 4 und 5 zeigen einige wichtigere Ausführungsformen des Kernes; bei diesen Darstellungen wurden der größeren Deutlichkeit wegen die Grenzen zwischen dem Kerne und dem porösen Teil durch punktierte Linien angedeutet, obwohl in der Wirklichkeit der Übergang des massiven Teiles in den porösen ein ganz allmählicher ist.

In Fig. 2 besteht der Kern *a* aus einer metallischen Schicht gleicher Stärke, welche sich nach und nach in den porösen Teil *b* verzweigt. In Fig. 3 hat der Kern die Gestalt eines Gitters; in Fig. 4 besteht derselbe aus einer mit Rippen *e* und zahlreichen Zacken *f* versehenen Platte *a*.

In Fig. 5 ist der poröse Teil *b* nur mit einem massiven Rahmen *a* umgeben, welcher, wie bei allen anderen Formen dieser Platten, ebenfalls mit dem porösen Teile ein einziges homogenes metallisches Stück bildet.

Platten für Akkumulatoren von solcher Beschaffenheit, daß zwischen Kern und porösem Teil keine Trennung besteht, weil beide Teile aus einer metallischen Masse bestehen, bieten den bisher bekannten gegenüber wesentliche Vorteile. Die Bildung des Superoxydes erfolgt in einer durchaus gleichmäßigen Weise nach und nach auf der äußeren Oberfläche aller Zwischenräume der porösen Schicht, ohne jedoch die wichtigen Verbindungsstellen (*d* in Fig. 1) zwischen Kern und porösem Teil angreifen und zerstören zu können, weil eben zwischen diesen Bestandteilen der Platte keine Trennung und keine Spalten vorhanden sind.

Die Stromzuführung kann vollständig gleichmäßig auf der ganzen Oberfläche des Kernes und des porösen Teiles erfolgen, wo-

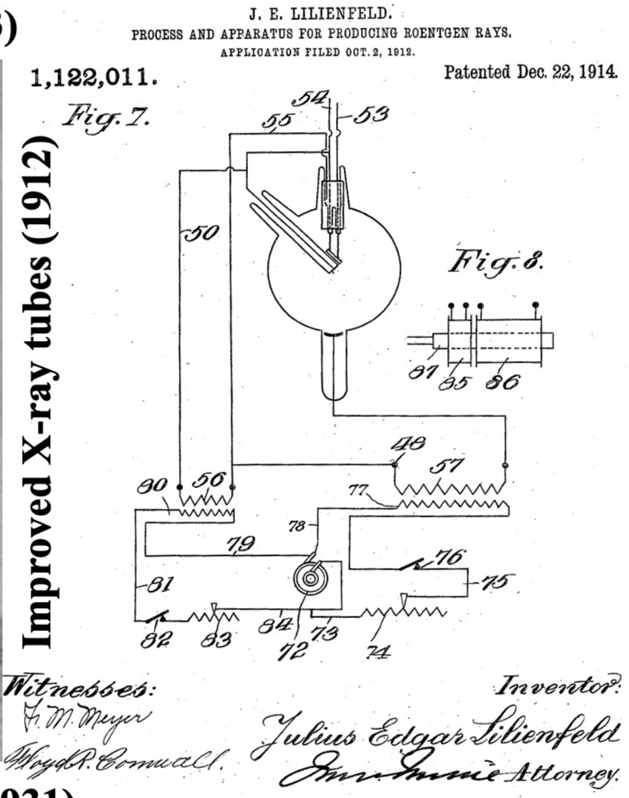
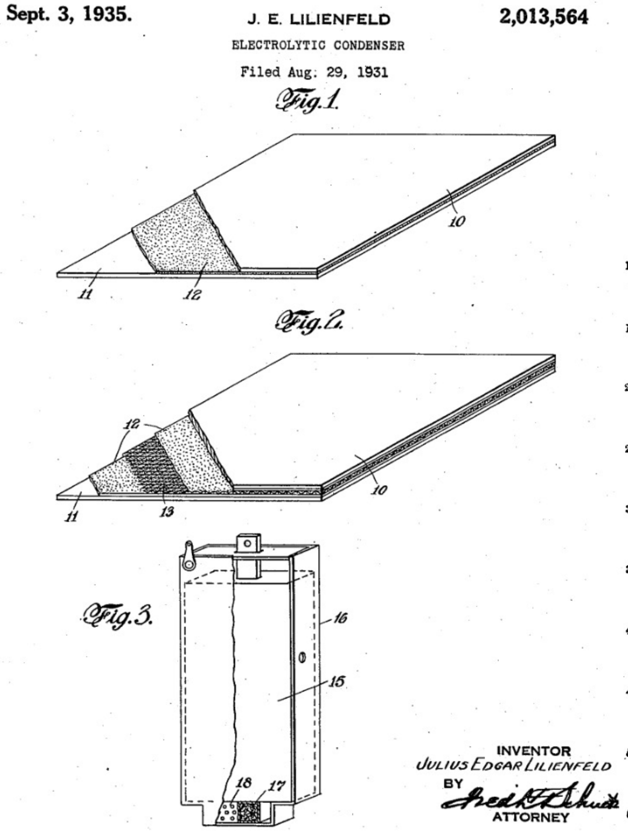
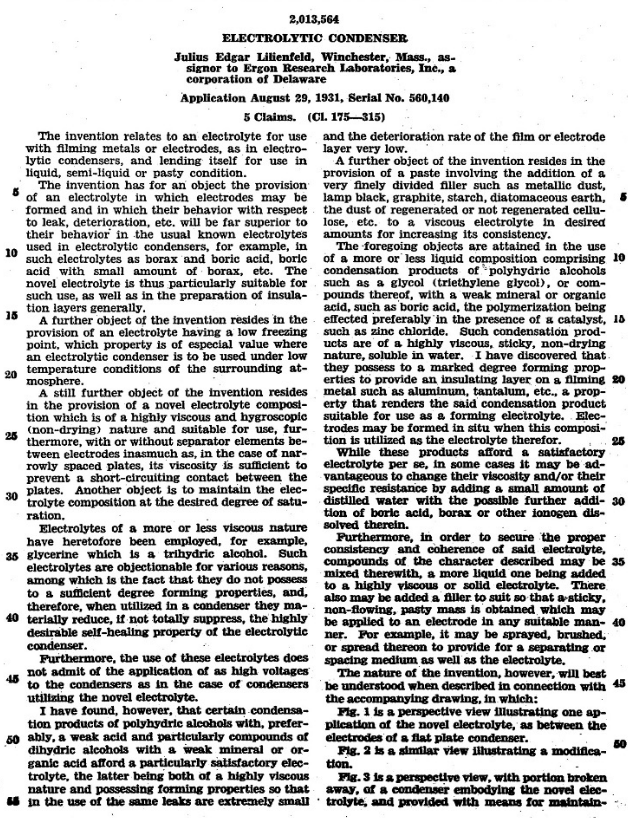
Julius Edgar Lilienfeld (1882–1963)







UNITED STATES PATENT OFFICE

2,013,564

ELECTROLYTIC CONDENSER

Julius Edgar Lilienfeld, Winchester, Mass., assignor to Ergon Research Laboratories, Inc., a corporation of Delaware

Application August 29, 1931, Serial No. 560,140

5 Claims. (Cl. 175—315)

The invention relates to an electrolyte for use with filming metals or electrodes, as in electrolytic condensers, and lending itself for use in liquid, semi-liquid or pasty condition.

The invention has for an object the provision of an electrolyte in which electrodes may be formed and in which their behavior with respect to leak, deterioration, etc. will be far superior to their behavior in the usual known electrolytes used in electrolytic condensers, for example, in such electrolytes as borax and boric acid, boric acid with small amount of borax, etc. The novel electrolyte is thus particularly suitable for such use, as well as in the preparation of insulation layers generally.

A further object of the invention resides in the provision of an electrolyte having a low freezing point, which property is of especial value where an electrolytic condenser is to be used under low temperature conditions of the surrounding atmosphere.

A still further object of the invention resides in the provision of a novel electrolyte composition which is of a highly viscous and hygroscopic (non-drying) nature and suitable for use, furthermore, with or without separator elements between electrodes inasmuch as, in the case of narrowly spaced plates, its viscosity is sufficient to prevent a short-circuiting contact between the plates. Another object is to maintain the electrolyte composition at the desired degree of saturation.

Electrolytes of a more or less viscous nature have heretofore been employed, for example, glycerine which is a trihydric alcohol. Such electrolytes are objectionable for various reasons, among which is the fact that they do not possess to a sufficient degree forming properties, and, therefore, when utilized in a condenser they materially reduce, if not totally suppress, the highly desirable self-healing property of the electrolytic condenser.

Furthermore, the use of these electrolytes does not admit of the application of as high voltages to the condensers as in the case of condensers utilizing the novel electrolyte.

I have found, however, that certain condensation products of polyhydric alcohols with, preferably, a weak acid and particularly compounds of dihydric alcohols with a weak mineral or organic acid afford a particularly satisfactory electrolyte, the latter being both of a highly viscous nature and possessing forming properties so that in the use of the same leaks are extremely small and the deterioration rate of the film or electrode layer very low.

A further object of the invention resides in the provision of a paste involving the addition of a very finely divided filler such as metallic dust, lamp black, graphite, starch, diatomaceous earth, the dust of regenerated or not regenerated cellulose, etc. to a viscous electrolyte in desired amounts for increasing its consistency.

The foregoing objects are attained in the use of a more or less liquid composition comprising condensation products of polyhydric alcohols such as a glycol (triethylene glycol), or compounds thereof, with a weak mineral or organic acid, such as boric acid, the polymerization being effected preferably in the presence of a catalyst, such as zinc chloride. Such condensation products are of a highly viscous, sticky, non-drying nature, soluble in water. I have discovered that they possess to a marked degree forming properties to provide an insulating layer on a filming metal such as aluminum, tantalum, etc., a property that renders the said condensation product suitable for use as a forming electrolyte. Electrodes may be formed in situ when this composition is utilized as the electrolyte therefor.

While these products afford a satisfactory electrolyte per se, in some cases it may be advantageous to change their viscosity and/or their specific resistance by adding a small amount of distilled water with the possible further addition of boric acid, borax or other ionogen dissolved therein.

Furthermore, in order to secure the proper consistency and coherence of said electrolyte, compounds of the character described may be mixed therewith, a more liquid one being added to a highly viscous or solid electrolyte. There also may be added a filler to suit so that a sticky, non-flowing, pasty mass is obtained which may be applied to an electrode in any suitable manner. For example, it may be sprayed, brushed, or spread thereon to provide for a separating or spacing medium as well as the electrolyte.

The nature of the invention, however, will best be understood when described in connection with the accompanying drawing, in which:

Fig. 1 is a perspective view illustrating one application of the novel electrolyte, as between the electrodes of a flat plate condenser.

Fig. 2 is a similar view illustrating a modification.

Fig. 3 is a perspective view, with portion broken away, of a condenser embodying the novel electrolyte, and provided with means for maintain-

CONDENSER WITH METALIZED DIELECTRIC

Eberhard Traub, Stuttgart, Germany, assignor to
Robert Bosch Gesellschaft mit beschränkter
Haftung, Stuttgart, Germany

Application July 6, 1937, Serial No. 152,157
In Germany August 4, 1936

14 Claims. (Cl. 175—41)

This invention relates to condensers with metalized dielectric in which therefore no independent metal foil is used but for the making of which a dielectric serves upon which the condenser covering is produced by spraying, rolling, in particular, however, by atomization (cathode atomization) or by the vaporization of metal or is otherwise directly produced. In such condensers contact difficulties easily result at the current connections, in particular when the condenser covering is very thin, for example if it is less than 0.002 mm. or 0.001 mm.

In such condensers in order to secure a lasting current connection it has been proposed according to application Serial No. 22,072 that an edge of the dielectric provided with the metallic covering is turned down 180° so that the metal covering will come on the outside. The contact for the current is attached to the turned down edges left free after the assembling. If such a condenser is constructed only of metalized dielectric then we shall have on the turned down edges a direct contact with the metalized surface of the adjacent layers of the same potential. However if we use besides the metalized also intermediate layers of non-metalized dielectric then measures must be taken if we wish to obtain a mutual contact of the adjacent layers of the same potential.

We may obtain a simple condenser structure according to the invention if we turn down not only the edge of the metalized dielectric layers but also the edge of the non-metalized dielectric layers, and that in such manner that the folded edges of the non-metalized dielectric layers will come within the turned down fold of the metalized dielectric.

In the drawing is shown an embodiment of the invention and in particular the drawing shows a coiled condenser in general view and partial section, in which the section shows the individual dielectric layers in considerably increased thickness. A—A indicates in the drawing the center line of the condenser. For the construction of the coil, in the embodiment shown, metalized paper is employed, especially paper which has received vaporized metal (zinc or cadmium for example) or has been metalized by cathode atomization. By *a* is designated the one and by *b* the other metalized paper strip. *c* is the metal coating upon the strip *a* and *d* the metal coating upon the strip *b*. The metal coatings or coverings have a thickness of about 0.0001 mm. *f* and *g* are two non-metalized paper strips. The non-metalized paper strips are, just like the metalized paper strips, turned down at one edge of the condenser by 180° and that in such a way that the turned down edges of the strips *f* and *g* will lie within the turned down folds of the strips *a* and *b*.

On the front sides of the condenser on the turned down edges of the metal coverings *c* and *d* lying exposed to the outside is attached the connection for the current. It consists of a metal coating *h* which is specially produced by spraying thereupon. The metal covering *h* should not be too thick as otherwise it will be too brittle. It must be merely so thick (say 0.3 to 0.5 mm.) that a terminal wire can be soldered thereon. In the drawing *i* and *k* indicate the two connecting wires.

The individual coatings do not have in a radial direction, as is shown in the drawing for sake of clearness, an interval between one another but are rolled directly on one another.

In the example of the invention between the two metalized paper strips *a* and *b* only one non-metalized paper strip *f* and *g* is used respectively. If we use between the metalized dielectric coatings a plurality of non-metalized dielectric coatings then we turn down the edges of all non-metalized coatings and that in such fashion that the folded edges of the metalized coatings will overlap them.

What is claimed is:

1. A condenser comprising successive layers of metalized and non-metalized insulating material arranged so that the metalized and non-metalized layers alternate with each other, alternate metalized layers being brought into contact with each other at one edge by folding over one edge of said alternate metalized layers and the cooperating non-metalized layers so that the folded edge of a non-metalized layer lies within the fold and the metal coating of the metalized layer faces the outside of the fold.

2. A condenser comprising successive layers of metalized material separated by layers of non-metalized material, one edge of a metalized layer and the adjacent edge of a non-metalized layer being folded upon themselves and the opposite edge of the next metalized layer and the adjacent edge of a non-metalized layer being folded upon themselves so that each folded edge of the non-metalized layer lies within a fold and the metal coating of each metalized layer faces the outside of a fold, the metal coated corners of such folds providing metal coated edges lying exposed at the sides of said condenser, and a metal coating connecting said coated edges.

3. A condenser comprising strips of metalized and non-metalized insulating material wound up in the form of a roll to provide successive layers of metalized insulating material separated by layers of non-metalized insulating material, one edge of each metalized strip and the adjacent edge of each non-metalized strip being folded upon themselves so that the folded edge of each non-metalized strip lies within a fold and the metal coating of each metalized strip faces the outside of a fold and contacts the adjacent coating of the same polarity, the folded edges of one set of cooperating metalized and non-metalized strips lying adjacent to but spaced from the unfolded edges of the next set of cooperating metalized and non-metalized strips, the metal coated corners of such folds providing continuous metal-coated edges lying exposed at the sides of said condenser, and condenser terminals connected to said fold corners.

2 **2,244,090**

4. A condenser comprising at least two strips of insulating material wound up in the form of a roll, one side of one of said strips being provided with a coating of metal, an edge of a coated strip and an edge of an uncoated strip being folded upon themselves so that the folded edge of the uncoated strip lies within the fold and the metal coating of the coated strip faces the outside of the fold to thereby provide a continuous metal-coated edge exposed at the side of the condenser to form a surface for connection of a terminal of the condenser.

5. A condenser comprising two strips of metalized paper and at least two strips of non-metalized paper wound up in the form of a roll with the metalized strips alternating with the non-metalized strips, one edge of one metalized strip and the adjacent edge of a non-metalized strip being folded upon themselves and the opposed edges of the other metalized and non-metalized strips being folded upon themselves so that each folded edge of the non-metalized strip lies within a fold and the metal coating of each metalized strip faces the outside of a fold and contacts the adjacent coating of the same polarity, the metal coated corners of such folds providing continuous metal-coated edges lying exposed at the sides of said condenser, and condenser terminals connected to said fold corners.

6. A condenser as set out in claim 5, in which the thickness of the metalization is about 0.0001 mm.

7. A condenser comprising successive layers of metalized and non-metalized paper, one edge of adjoining metalized and non-metalized layers being folded upon themselves at an angle of 180° so that the metal coating of the metalized layer faces the outside of the fold with the folded edge of the non-metalized layer within the fold, the metal-coated corners of such folds lying exposed at the sides of the condenser, and a metal coating applied to and connecting said fold corners.

8. A condenser comprising a plurality of superposed layers of metalized dielectric and intermediate layers of non-metalized dielectric, alternate metalized layers of said metalized dielectric being brought into metallic contact with each other by folding over the edges of said layers and the cooperating non-metalized layers so that the metalization faces the outside of the folds and provides a plurality of metal-coated folded edges at opposite sides of the condenser, the folded edges of the non-metalized layers each lying within a fold.

9. A condenser as set out in claim 8, including a metal coating connecting said metal-coated folded edges and providing condenser terminals.

10. A condenser as set out in claim 8, in which the thickness of the metalization is less than 0.001 mm.

11. A condenser comprising two strips of metalized paper and at least two strips of non-metalized paper wound up in the form of a roll with the metalized strips alternating with the non-metalized strips, one edge of one metalized strip and the adjacent edge of a non-metalized strip and the opposed edges of the other metalized and non-metalized strips being folded longitudinally upon themselves at an angle of 180° so that each folded edge of the non-metalized strips lies within a fold of the metalized strips and the metal coating of each metalized strip faces the outside of a fold and is in metalic contact with the next succeeding coating of the same polarity, the metal-coated corners of said folds providing continuous metal-coated edges lying exposed at and forming the sides of said condenser, a terminal metal layer applied to each side of said condenser and electrically connecting said metal-coated corners, and a terminal conductor soldered to each terminal metal layer.

12. A condenser as set out in claim 11, in which the metalization has a thickness of about 0.0001 mm.

13. A condenser comprising two strips of metalized paper and at least two strips of non-metalized paper wound up in the form of a roll with the metalized strips alternating with the non-metalized strips, the metalization of each metalized strip extending to one edge thereof, a non-metalized margin remaining along the opposite edge of each strip, the metalized edge of one metalized strip and the adjacent edge of a non-metalized strip being folded upon themselves and the metalized edge of the other metalized strip and the adjacent edge of the other non-metalized strip being folded upon themselves so that each folded edge of the non-metalized strips lies within a fold and the metalization of each metalized strip faces the outside of a fold and contacts the adjacent metalization of the same polarity, the metal coated corners of such folds providing continuous metal coated edges lying exposed at and forming the sides of said condenser, and a metal coating applied to and connecting said fold corners at each side of said condenser.

14. A condenser comprising two strips of metalized paper and at least two strips of non-metalized paper wound up in the form of a roll with the metalized strips alternating with the non-metalized strips, the metalization of each metalized strip having a thickness of less than 0.001 mm. extending to one edge thereof, a non-metalized margin remaining along the opposite edge of each strip, the metalized edge of one metalized strip and the adjacent edge of a non-metalized strip being folded upon themselves and the metalized edge of the other metalized strip and the adjacent edge of the other non-metalized strip being folded upon themselves so that each folded edge of the non-metalized strips lies within a fold and the metalization of each metalized strip faces the outside of a fold and contacts the adjacent metalization of the same polarity, said strips being arranged with the metalized edge of one metalized strip and the non-metalized edge of the other metalized strip adjacent to but spaced from each other, the metal coated corners of the folded edges of said metalized strips being arranged alternately at opposite sides of the condenser to provide continuous metal coated edges lying exposed at and forming the sides of said condenser, and a metal coating applied to and connecting said exposed folded metal coated edges at each side of said condenser.

RESUME OF INTELLIGENCE GAINED BY INVESTIGATION

. Several years ago The Robert Bosch Company undertook the development of fixed paper capacitors which had the metal foil used in the conventional fixed paper capacitor replaced by the application of a very thin metallic coating directly onto the paper dieelectric. This Company has produced many millions of these condensers for use in both alternating and direct current circuits with very satisfactory results. After a careful study of the manufacturin processes involved in the production of this type of conden and an evaluation of the advantages and economies which can be gained by the use of this type of condenser as compared with the conventional type the following recommendation is made. If a manufacturer of fixed paper condensers in the United States wished to go into the production of metalized paper condensers and was willing to spend about 25,000 dollars for the design and production of the two special machines, he would be in a position to produce fixed paper capacitors which are about 40% smaller than the paper and foil type and which could be produced at 20% reduction in cost. These advantages would very quickly pay for the investment in the special

Chief, Engineering & Technical Service
Office of the Chief Signal Officer
Pentagon Bldg., Room 3E-348
Washington 25, D. C.

SUBJECT: Shipment of German Capicator Machine to Ft. Monmouth

1. The writer has recommended to Col. Urhane and Major Neal Crane, Technical Liaison Division, O C Sig. O, Hq. Com. Z, APO 887, that the Signal Corps evacuate for shipment to Ft. Monmouth one machine and the control equipment for the manufacture of paper capacitors from the Bosch plant at Stuttgart, Germany.

2. The process is covered by U.S. Pat. 2,244,090 in the custody of the Alien Property Custodian, who has requested TIIC to secure additional information on the process, which has been done by investigator F. E. Henderson, loaned by the Western Electric Co. His report on the process should be available from TIIC, Washington, in about 30 days. Mr. Henderson may be reached for first-hand information, if and when desired, at the Point Breeze plant of Western Electric at Baltimore after 20 August.

3. Bosch states that they have furnished about 40 million capacitors of this type to the German military. The units are far more compact than anything we have produced and are familiar to all Signal Corps personnel who have examined captured German radio equipment. However, an important item that is probably not known is that they are self-healing on repeated breakdowns caused by over-voltage surges. The value of this feature, if true, is too evident to be dwelt on here.

4. This self-healing feature probably explains the Germans would risk using a single sheet of 0.4-mil Kraft paper as a suitable capacitor dielectric for a m imum working voltage of 250-dc.

5. The salient features of the construction are these: An extremely thin film of bakelite varnish is applied to one side of the paper, following which zinc vapor is applied in a vacuum. The thickness of the zi film on the paper is about 2 microns. Consequently, should a voltage break-down occur, due to a pin hole o weak spot in the dielectric, the extremely thin film o zinc acts as a fuse and the capacitor practically alwa "burns open" instead of a short-circuiting, as is the c with the conventional rolled paper, metal foil, capacit

6. The remainder of the construction features a adequately described in the patent. The machine for ac plishing the above operations is very ingeneously desi and for this reason it is considered desirable to have one available for examination in the event manufacture of these capacitors in the U.S. is decided upon.

7. It is recommended that SCGSA be requested to investigate the information referred to in Para. 2 as it becomes available and to furnish their comments and recommendations as to the practicability of initiating the manufacture of these capacitors in the U.S. either by means of a development contract, or other suitable means.

BOSCH METALLIZED PAPER CONDENSER

Another of the many developments discovered in Germany which has aroused wide-spread interest among American manufacturers is an ingenious machine which applies a vaporized zinc coating to paper used in the manufacture of electrical condensers.

The patent for this process was on file in this country in the office of the Alien Property Custodian. An American condenser manufacturer who had contracts with the Army and Navy attempted to use this process because the condensers produced by its application were excellently suited for the equipment requirements under the contracts. However, the manufacturer was unsuccessful in his efforts to utilize the information thus available because of inability to comprehend certain details. The Alien Property Custodian requested that additional information be obtained for the benefit of this manufacturer and others, and American investigators undertook to obtain it.

The inventor of the process and the working machine were found at the Robert Bosch plant in Stuttgart where the development resulted from wartime research. The condenser has several important advantages over the conventional types manufactured in this country. A very thin metallic coating applied directly to the paper dielectric is used in place of the metal foil used in condensers produced domestically. This feature permits automatic healing after a breakdown occurs which is due to the fact that the very thin vaporized metallic film completely evaporates around the point of the breakdown so that an adequate insulation margin is again provided. Thus, numerous breakdowns may occur before the effective value of the condenser area is reduced beyond a workable limit. Because of this characteristic the condenser can be operated at 20 per cent to 50 per cent higher voltage than is possible with the conventional type. Also, the condensers are 40 per cent smaller and manufacturing costs can be approximately 20 per cent less than for those made by American firms.

The degree of interest that American industry has in this development is indicated by the fact that since the equipment has been evacuated to this country and condensers have been manufactured by the machinery which was set-up and put into operation in the Western Electric Company Hawthorne Plant in Chicago, the leading domestic manufacturers of condensers have become vitally interested in using the process.

Many millions of condensers are used in this country in the Electric and Electronics and Communications industries, and radio and radar could not have been perfected without them. This new process will revolutionize the manufacturing of these condensers, reducing their size and their cost and improving the reliability of the apparatus using them.

Information pertaining to this development is contained in Reports No. PB-39361 and PB-39361-S available through the Office of Technical Services of the Department of Commerce.

See attached letters.

Figure 6.106: The United States acquired Eberhard Traub's metalized paper capacitor technology in 1945 [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards].

6.5.6 Printed Circuits

While moving from large vacuum tubes to small transistors greatly helped to miniaturize and simplify electronics, the development of printed circuit boards was another major step in microelectronics. In printed circuits, electronic components are attached to an insulating board that is covered with etched metal lines for wires, avoiding the labor and bulkiness involved in connecting separate physical wires to each component. A closely related technological development was multi-pin connectors, which could be used without printed circuits but became even more advantageous when used together with printed circuits.

As shown on pp. 1090 and 2766–2777, Albert Hanson (German, 18??–19??) filed patent applications on printed circuits and multi-pin connectors in 1902 and 1903. From the available documentation, it is not clear how far he got in implementing his designs, although the highly detailed nature of the patents suggests that he may well have built and tested printed circuits and multi-pin connectors.

Mathias Nowottnick, an engineering professor at the University of Rostock, noted that printed circuit technology, apparently based on Hanson's patents, was being used by at least three German companies by 1927–1932 [Nowottnick 2014, p. 4]:

1927 Telefunken, Verdrahtung von Bauteilen mittels Messingstreifen.	1927 Telefunken, wiring of components using brass strips.
1930 Hescho-Werke in Hermsdorf Aufdrucken von Leiterzügen auf Keramiksubstrat mittels Siebdrucktechnik (stellt heute noch die Grundlage für die Dickschichttechnik dar!)—"Gedruckte Schaltung".	1930 Hescho Works in Hermsdorf Imprinting of conductors on ceramic substrate using screen printing technology (still the basis for thick-film technology today!)—"printed circuits."
1932 erste Leiterplatte mit genieteten Metallstreifen, Sachsenwerk Licht und Kraft AG [Fig. 6.108]	1932 first printed circuit board with riveted metal strips, Sachsenwerk Light and Power AG [Fig. 6.108]

Wolfgang Scheel, a longtime department head of the Fraunhofer Institute, named additional German companies that were among the first to use printed circuits [Manfred Frank 2003, p. 2]:

Lassen Sie mich zunächst feststellen, dass die Leiterplatte in diesem Jahr [2003] ihren 100. Geburtstag feiert. Der Berliner Hanson hat dafür das Patent 1903 angemeldet. Ferner möchte ich anmerken, dass als Pionierfirmen auf dem Gebiet der Leiterplatteentwicklung in Deutschland die Sachsenwerk Licht und Kraft AG Niedersedlitz, die Ruwelwerke Geldern, die Lackwerke Peters in Kempen und die Isola AG in Düren zu nennen sind.	Let me first note that the printed circuit board celebrates its 100th birthday this year [2003]. Hanson from Berlin filed the patent for it in 1903. I would also like to note that the pioneering companies in the field of printed circuit board development in Germany are Sachsenwerk Licht und Kraft AG Niedersedlitz, Ruwelwerke Geldern, Lackwerke Peters in Kempen and Isola AG in Düren.

Paul Eisler (Austrian, 1907–1992) studied engineering at the University of Vienna, graduated in 1930, and worked in electrical engineering, during which time he apparently became familiar with then-current German and Austrian printed circuit technologies that were based on Hanson's original patents. In 1936 Eisler fled to the United Kingdom, taking his knowledge of printed circuit technologies with him, and he immediately began building printed circuits upon his arrival there [Eisler 1989; Medawar and Pyke 2000]. He brought the technology to the attention of the British government during World War II and filed patent applications on it in 1944 (pp. 1092 and 2779–2795). Some U.S. officials discovered Eisler's work and incorporated simple printed circuits into proximity fuses for artillery shells that were used in late 1944 and 1945, but otherwise Allied countries do not seem to have harnessed the potential of printed circuits during the war.

In contrast, as shown on pp. 1093 and 2796–2799, printed circuits were in "wide use" in wartime Germany (presumably having grown far beyond just Telefunken, Hescho-Werke, and Sachsenwerk since ∼1930), and all of that printed circuit technology was transferred to the United States on a large scale after the war by people such as longtime Bell Telephone Laboratories engineer Todos Odarenko.

The final step in the development of printed circuits came when Rudolf Strauss (German, 1913–2001, Fig. 6.111) developed the wave soldering method for the fully automated manufacturing of printed circuits, or surface mount technology (SMT), from 1951 to 1955 [rondinax.wordpress.com/2014/01/31/rudolf-strauss-1913-2001-a-key-player-in-the-rondinax-and-rondix-story/]. See also pp. 2800–2806. (Was Strauss truly the original creator of wave soldering, or did he bring that method with him from the German-speaking world, just as Eisler apparently brought printed circuits?)

Historians of science Jean Medawar and David Pyke emphasized the importance of the development of printed circuits [Medawar and Pyke 2000, p. 93]:

> Rudolf Strauss [...] met and became friends with Paul Eisler, a refugee from Austria, who had invented the printed electrical circuit board, which revolutionized the electronics industry. Strauss invented a technique for soldering thousands of electric connections in one operation. His 'wave soldering' machine, built in 1958, is still being made in a sophisticated form all over the industrial world. [...]
>
> Recognition of Eisler's work took years. In late 1957 Lord Hailsham told the Royal Society that he rated the printed electric circuit as important an invention as penicillin or atomic fission.

Note that Medawar and Pyke described Eisler as the inventor of printed circuits, as have many other modern historians. While Eisler played a critical role in transferring printed circuit technology out of the German-speaking world and producing the first printed circuits in Allied countries, it seems clear from the historical record that Albert Hanson was the original inventor in 1902, and that multiple companies in the German-speaking world were building and selling printed circuits several years before Eisler ever built his first printed circuit board.

Boris Chertok, who led some of the Soviet missions removing German technologies after World War II, mentioned the widespread German use of sophisticated multi-pin connectors. Those likely went along with printed circuits, since printed circuits were in wide use and both multi-pin connectors and printed circuits traced back to Albert Hanson's inventions. Chertok also described the transfer of many other advanced electronics technologies to the Soviet Union (pp. 2807–2812).

Much more archival research is needed to reconstruct the detailed history and extent of research and development of printed circuits in the German-speaking world, as well as how that work was transferred to other countries during and after the Third Reich.

Albert Hanson (18??–19??) filed detailed patent applications on printed circuits and multi-pin connectors 1902–1903

COMPLETE SPECIFICATION.

Improvements in Automatic Switchboards for Telephone and like Exchanges.

I, Albert Parker Hanson, of 6 Lützow, Charlottenburg, in the Kingdom of Prussia, Engineer, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention relates to the construction and disposition of apparatus in automatic exchanges, that is, centrals in which a number of selective switches, worked from a distance, are installed. Such plants are for example employed in so-called "automatic" telephone service. A single selective mechanism proper of such a plant with its box or frame will be called here the "switch", while the imaginably closed bounded field within which the lines leading to or past the switch are made accessible for purposes of making contact will be called a "contact field". A bank of contacts is a number of conducting bodies so arranged and held together as to present a contact field to the switch.

The purpose of my invention is to provide methods by which simplicity in manufacture, ease of transport and installation, accessibility in operation, facility in handling in service and economical use of space are insured.

These advantages I secure singly or in various combinations by incorporating numbers of contact banks into more or less rigid rows, independently of the switches to which they belong, and providing for their advantageous disposition at the central.

A very important feature of the invention is its allowing of many and varied forms each bringing with it a series of practical arrangements. Thus, in the forms hereinafter described in illustration of the invention, the advantages above enumerated are secured in an advancing degree even while the cost of manufacture per unit of apparatus is constantly decreasing.

Arrangements of wires or other conductors running parallel to each other, practically like zither-strings, and forming contact fields for switches arranged in a row parallel to them are already known—see British Patents, No. 8607/'94 and 23239/'97, also U.S. Patent No. 626983, Decker Fig. 15.

My invention, however, is not affected by these and similar arrangements as heretofore applied. The contact banks employed by me are such as—in order

PROVISIONAL SPECIFICATION.

Improvements in or connected with Electric Cables and the Jointing of the same.

I, Albert Parker Hanson, of 43 Dorotheenstrasse, Berlin, in the Kingdom of Prussia, Engineer, do hereby declare the nature of this invention to be as follows:—

My invention relates to improvements in or connected with electric cables and the jointing of the same, by means of which certain advantages are obtained; and it is specially though not exclusively applicable for telephone exchange purposes where it is desirable to have a large number of conductors led to the switch boards or switching devices within very small compass and yet with each conductor or group of conductors readily accessible for jointing, replacing or other purposes.

A cable constructed under my invention may be broadly stated to be one in which a number of conductors are arranged between layers of paper or other suitable material the said material being when desired perforated or arranged so as to leave gaps or openings for jointing or other desired purposes.

In order that the nature of my invention may be more readily understood I shall proceed to briefly refer to certain contemplated forms thereof which will I anticipate give good results in practice. In all the forms hereinafter mentioned the conductors may be bare or insulated in any convenient manner and they may be arranged singly or in pairs for working on metallic circuit and they may be crossed at intervals for the purpose of avoiding induction sounds.

In one contemplated form, the conductors are spaced apart and glued or cemented to sheets of paper and these are built up so that the cable consists of alternate layers of separated wires and of paper paraffined or otherwise treated when desired. Instead of paper, fabric or tissue of any desired material may be employed.

In another contemplated form instead of separating the conductors by flat strips or sheets of paper or other material they may be separated by a single sheet or strip which is folded or corrugated longitudinally. The wires are then placed at the bottoms of the folds or corrugations and the upper parts of the said material are then bent over laterally so that each conductor lies in a kind of elongated pocket and is completely separated from its neighbours.

In a third form the conductors may simply rest between two layers of insulating material without being either cemented to or folded into the said material.

In a fourth contemplated form instead of separating the conductors by continuous lengths of paper or other material I use a number of short strips or layers of the latter spaced some distance apart so as to leave the conductors visible and accessible at intervals.

In a fifth contemplated form instead of using flat strips or layers, whether long or short, I employ corrugated strips or sheets, either long or short, and

COMPLETE SPECIFICATION.

Improvements in Soldering Fluxes.

We, FRY'S METAL FOUNDRIES LIMITED, of Tandem Works, Merton Abbey, London, S.W.19, a British Company, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement :—

This invention relates to rosin soldering fluxes. By the term " rosin " we mean the naturally occurring product, known sometimes as colophony, gum rosin, wood rosin or tree rosin, which is obtained from coniferous trees such as the pine tree.

A measure of the activity of a rosin flux is its spreading power on copper as determined by a spreading test. One known type of spreading test consists in placing on a thin sheet of copper a pellet, weighing 0.2 gms., of solder containing 42% by weight of tin and 58% by weight of lead. The pellet is surrounded with a small quantity of the flux under test, and the plate is then heated to 300° C. to melt the solder, and maintained at that temperature until the molten solder spreads no further. The average diameter of the area covered by the solder after the test is then determined.

Various organic activating agents have been proposed for incorporation in rosin fluxes for the purpose of improving their spreading power. Thus it has been proposed to incorporate in the flux from about 0.2—8% of cetyl pyridinium bromide (" Fixanol " C). " Fixanol " is a Registered Trade Mark.

Taking the diameter of the spread of the solder in accordance with the above test, when fluxed with plain rosin, as 1.00, the diameter of spread when the solder was fluxed with rosin activated with 4% by weight of " Fixanol " C was found to be 1.30.

One object of the invention is to effect a further improvement in the spreading power of rosin soldering fluxes.

According to the invention, the spreading power of rosin soldering fluxes is improved by incorporating therein up to 5% by weight, measured on the weight of the rosin, of hydrobromide of morpholine or of a hydrobromide of an N-alkyl substituted derivative of morpholine.

We find that best results are achieved with a flux containing up to 2% by weight of morpholine hydrobromide, the rest rosin, or a flux containing up to 4% by weight of N-methyl or N-ethyl morpholine hydrobromide, the rest rosin.

When such fluxes were tested by the above test the following results were obtained :—

Activating Agent.	*Spreading Factor.*
1% by weight morpholine hydrobromide	1.80
1% by weight N-methyl morpholine hydrobromide ..	2.30
2% by weight N-ethyl morpholine hydrobromide ..	2.27

In the case of fluxes for use when soldering electrical connections and for other applications in which it is of extreme importance that the residue should be substantially non-corrosive, we find it desirable to include in the flux a proportion of cetyl pyridinium bromide (" Fixanol " C) and to restrict the upper limit of the content of the morpholine derivative to 4%. The invention accordingly includes a rosin soldering flux containing up to 5% of " Fixanol " C and 0.5—4% of N-methyl morpholine hydrobromide or N-ethyl morpholine hydrobromide. These fluxes are found to give a residue which is substantially non-corrosive. The following

6.5.7 Integrated Circuits

Even further miniaturization of electronics required moving from individual electronic components to integrated circuit chips that could contain large numbers of components on the same semiconductor substrate.

In 1949, Werner Jacobi (German, 1904–1985) filed a West German patent application on integrated circuits on behalf of Siemens & Halske. Since there were a large number of German inventors who filed patents on their wartime work when the (West) German patent office reopened in 1949, it is quite likely that Jacobi's patent application was based on experimental work that he had conducted at Siemens & Halske during the war (pp. 1096 and 2816–2817).

Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) developed advanced semiconductor devices for Germany in Prague during the war. After the war he was extensively interrogated by the United States and then moved to the United States (as part of Operation Paperclip), where he filed patents on transistors, integrated circuits, and light emitting diodes. See pp. 1074, 1097, 2757–2763, 2818–2832, and 2895–2910. Lehovec's integrated circuit designs may well have been based on wartime work, but even if they were early postwar ideas, they preceded the claims of American engineers who later worked on integrated circuits.

Other German-speaking scientists developed transistor fabrication methods that made integrated circuits practical:

- Herbert Kroemer (German, 1928–) invented the drift transistor in 1953 or earlier, the double-hetero-structure laser diode in 1963, and III-V semiconductor heterostructures in 1966 or earlier. See pp. 1111, 2833–2845, and 2917–2922. He won the Nobel Prize in Physics in 2000 (p. 1104).

- Jean Hoerni (Swiss, 1924–1997) and Eugene Kleiner (Austrian, 1923–2003) devised methods of manufacturing silicon transistors at Fairchild Semiconductor; see pp. 1101 and 2846–2861. Through Fairchild and their later companies and investments, they also helped to develop Silicon Valley.

- Karl Heinz Zaininger (German, 1929–) developed modern methods for fabricating field effect transistors (pp. 1102 and 2862–2876).

As shown on pp. 1103 and 2877–2887, Helmut Gröttrup (German, 1916–1981) and Jürgen Dethloff (German, 1924–2002) invented the smart card, or chip card, in 1966. Earlier, Gröttrup developed avionics systems in Germany during the war and led the German-speaking contributions to the postwar Soviet ballistic missile program (pp. 1874–1881).

As with transistors and printed circuits, much more research should be conducted to determine how much work on integrated circuits was conducted in the German-speaking world during the war, and how much impact German-speaking scientists and knowledge had on the postwar development of integrated circuits in other countries.

Werner Jacobi (1904–1985) filed a patent application on integrated circuits in 1949 (based on wartime work?)

Halbleiterverstärker

Patentiert im Gebiet der Bundesrepublik Deutschland vom 15. April 1949 an
Patenterteilung bekanntgemacht am 15. Mai 1952

Wenn der Halbleiter in der zur Zeit bekannten Form vielleicht auch nicht geeignet ist, in allen Fällen von Verstärkeranordnungen an die Stelle einer Elektronenröhre zu treten, so scheint seine Anwendung jedoch für bestimmte Zwecke vorteilhaft zu sein. So dürfte er sich u. a. besonders für Schwerhörigengeräte eignen. Aus dieser Zweckbestimmung heraus entsteht die Aufgabe, deren Lösung selbstverständlich auch für jegliche andere Anwendung des Halbleiterverstärkers grundsätzliche Bedeutung z. B. aus preislichen Gründen hat, einen solchen Halbleiterverstärker nicht nur billig, sondern auch raum-, gegebenenfalls auch gewichtssparend aufzubauen. Zur Lösung dieser Aufgabe wird erfindungsgemäß vorgeschlagen, auf den Halbleiter mehrere in verschiedenen Schalt- bzw. Verstärkerstufen wirkende Elektrodensysteme aufzusetzen.

Nimmt man z. B. an, daß der in der Figur als geschnittene Halbkugel gezeigte Halbleiter *K* einen Durchmesser von 2 mm hat, so können je nach der konstruktiven Gestaltung und Anordnung der einzelnen Elektroden mehrere Elektrodensysteme in je einem Abstand von 0,2 mm bei bekanntem Elektrodenabstand von 0,05 mm aufgesetzt werden, ohne daß eine gegenseitige Beeinflussung der einzelnen Systeme eintritt. Diese Elektrodensysteme können dann in bekannter Weise durch Kopplungsglieder zu einem mehrstufigen Halbleiterverstärker zusammengeschaltet werden.

Hierbei können die Kopplungsglieder gegebenenfalls aus einer Halbleiteranordnung bestehen, welche zusätzlich aufgewendet oder durch Einsatz von auf den Halbleiter schon aufgesetzten Elektrodensystemen gebildet werden. Zu diesem Zweck wird die sonst als Eingang dienende Elektrode als Ausgang des Kopplungsgliedes benutzt und umgekehrt, da der Halbleiterverstärker einen niederohmigen Eingang und einen hochohmigen Ausgang benötigt. Man erspart also auf Grund der vorliegenden Erkenntnis, den Halbleiter mit vertauschtem Eingang und Ausgang als Transformator zu benutzen, mit Rücksicht auf diese Eingangs- und Ausgangsverhältnisse besonders auszubildende Kopplungsglieder. In der Figur sind fünf solcher Systeme mit den beispielsweise einzuhaltenden Maßen schematisch angedeutet.

PATENTANSPRÜCHE:

1. Halbleiterverstärker, dadurch gekennzeichnet, daß auf den Halbleiter mehrere in verschiedenen Schalt- bzw. Verstärkerstufen wirkende Elektrodensysteme aufgesetzt werden.

2. Halbleiterverstärker, insbesondere nach Anspruch 1, dadurch gekennzeichnet, daß bestimmte Elektrodensysteme nach Vertauschung von Eingangs- in Ausgangselektrode und umgekehrt als Kopplungsglieder zwischen anderen Elektrodensystemen dienen.

Figure 6.112: Werner Jacobi filed a patent on integrated circuits in 1949, likely based on wartime work.

TRANSISTOR COMBINATIONS
Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts
Filed June 9, 1955, Ser. No. 514,220
5 Claims. (Cl. 250—211)

This invention relates to transistor combinations, more particularly to combinations by which signals can be amplified.

Among the objects of the present invention is the provision of novel transistor combinations which have improved amplification characteristics as compared to prior art combinations.

The above as well as additional objects of the present invention will be more clearly understood from the following description of several of its exemplifications, reference being made to the accompanying drawings wherein:

FIG. 1 is a representative showing, partly in schematic form, of one embodiment of a unipolar transistor;

FIG. 2 is a schematic showing of a modified unipolar transistor combination according to the present invention;

FIGS. 3 and 4 are diagrammatic views of prior art forms of unipolar transistors; and

FIGS. 5 and 6 are pictorial representations of modified unipolar semiconductor devices according to the invention.

A unipolar transistor was fully described by W. Shockley in an article, entitled "A Unipolar Field Effect Transistor," which appeared in the November 1952 issue of the Proceedings of the IRE, Volume 40, No. 11, pages 1365–1376. Briefly the device consists essentially of a semiconductor having a conducting channel with an adjacent equipotential layer or gate electrode and a space charged region in the semiconductor between the channel and the equipotential layer. By varying the potential between the channel and the equipotential layer, the effective channel width can be varied and the channel current which is being carried therein is similarly varied. When the current flows along the channel the potential thus varies along the channel, which in turn results in a potential variation between the channel and the equipotential layer. As a result, the width of the space charged region varies along the channel and with sufficiently high potentials imposed on opposite ends of the channel, the space charged region may extend completely over the channel rendering it insulating or may even cause breakdown if maintained. This limits the usefulness of the device. It is thus the intent of this invention to render these unipolar field effect transistors less susceptible to breakdown or alternatively, susceptible to much higher current gain, as well as reliability of operation when used with signal voltages of substantial amplitudes.

It has been found possible to improve the operating curve of the unipolar transistor so as to handle larger signal voltages as well as to produce much higher power gains, through provision of two parallel current flows in a unipolar transistor so as to maintain the width of the charged layer at a uniform dimension. This is readily accomplished as indicated by providing a potential drop along the gate electrode which is the same or similar to the voltage drop along the channel.

For better understanding of this invention refer to FIG. 1, wherein the combination here illustrated has a semiconductor body **10** with two portions **12**, **14** of opposite types of conductivity. Portion **12**, for example, is indicated as having p-conductivity and portion **14** n-conductivity. Between them there is a p–n junction **15** that is relatively elongated. Intermediate of the ends of the rectangular crystal **10** are two depressions **16** and **17**, the former extending down into the p-region of conductivity and the latter extending into the n-region of conductivity. These grooved areas extend fully across the face of the crystal and are readily produced by magnetostrictive cutting followed by a jet electrochemical etch, both techniques of which are well-known to the art. The thickness of the web formed in the crystal between the points of maximum depth of depressions **16** and **17** is preferably very thin, not over 20 mils thick, and preferably much thinner, in the order of 2 mils thickness. Of course, it is to be realized that this lower limit of distance between the two depressions is dictated by the structural strength requirements which the device must exhibit. However, for optimum operational characteristics the thin region separation is desirable although the crystal can readily be supported by outside insulators, such as plastic holders, etc.

At opposite ends of each portion **12**, **14** are positioned electrodes represented at **18**, **20**, **22**, **24**. A bias supply **25** is connected between a correspondingly located pair of electrodes **18**, **22**, on the respective semiconductor portions, to bias the portions in the direction that blocks the passage of current from one body to the other. In the construction of FIG. 1 the bias supply also impresses varying signals "E" between the same electrodes **18**, **22**.

Electrodes **18**, **20** are shown as connected to an output circuit **26** including a source of potential **28** and an output load **30**. Another output circuit **32** is similarly connected between electrodes **22** and **24** and similarly polarized. For purposes of discussion the n-conductivity having electrodes **22** and **24** is designated the "channel" while the p-region with its electrodes **18** and **20** is designated the "gate."

The entire combination of FIG. 1 makes a so-called unipolar transistor amplifier in which the junction **15** provides a space charge effect that is substantially uniform along its length. For the greatest uniformity the semiconductor portions **12**, **14** should have corresponding electrical resistivities, e.g. of the order of 5 ohm-centimeters, and the output circuits should be arranged to apply corresponding potentials so that there are corresponding potential gradations along the effective length of the junction in both the channel and gate portions. The resistivities are controlled by the concentration of doping ingredients added to the respective semiconductor bodies either by diffusion into the solid body, surface melting or by alloying with a liquefied mass from which the bodies are formed.

A feature of the construction of FIG. 1 is that two different amplified output signals are provided so that one can be used independently of the other as a monitor, for example. In addition, where maximum power output is desired, both output signals can be combined as by transformer coupling. This is made possible by the use of the two depressions **16** and **17** so that the dimension of the space charge region could materially effect the current flow in the channel. Herein, in FIG. 1, for one part of the circuit including load **30** the n-region is the channel and the p-region the gate, and for the other part of the circuit including load **34**, vice versa.

FIG. 2 shows a modified construction of the unipolar transistor type in which one region of conductivity is sandwiched between regions of opposite conductivity. The three regions are illustrated as **31**, **32**, **33**, being produced by techniques well-known in the art. Blocking bias, as well as incoming signals, are supplied by source **36** between the intermediate body **32** on the one hand, and the outer two which can be connected together. Electrodes **38**, **40**, **42**, **44**, **46** and **48** are provided on the individual bodies as in the construction of FIG. 1.

The junction construction of FIG. 2 also has two output circuits **52**, **56**. One of these is connected to intermediate body **32** as in the construction of FIG. 1. The second output circuit **56** is connected to both outer bodies **31**, **33** in parallel. As a result of this construction, signals in the sandwiched body are subjected to what corresponds to two space charge effects, one at each junction. The voltage amplification of this body will therefore be larger than that of the others. Moreover, signal currents in the outer bodies can be added together by the parallel output connection.

With the construction of FIG. 2 the amplified output is taken from load **54** while load **57** serves merely to maintain the space charge region relatively constant along the junction. For taking a useful output from both loads **54** and **57** depressions similar to those of FIG. 1 must be imposed in the n-regions **31** and **33** completely across the opposing faces of the crystal.

FIGS. 3 and 4 are cross-sectional representations of known prior art devices of the unipolar field effect type. In FIG. 3 the n-region designated as **61** has two electrodes **66**, **68** between which an output circuit can be connected. Bias, as well as incoming signals, are supplied between electrode **64** and one of the electrodes **66**, **68** using the p-region to produce the gate and the n-region as the channel. In this construction, as well as the construction shown in FIGS. 1 and 2, all of the electrodes are of a non-rectifying nature.

In FIG. 4, however, an area metal contact which extends fully across the width of the crystal is utilized to produce a space charged region which can thus serve as the modulating means for the current flow in the channel. A semiconductor body **70** designated for the purposes of this discussion as having a conductivity of the p-type has spaced output electrodes **72** and **74** of the non-rectifying kind and an intermediate electrode **76** of the rectifying metal type. Thus a space charge effect similar to that described above appears to be provided by the metal electrode **76** when it is electrically biased in the current blocking direction. The bias and the incoming signals are impressed between the metal electrodes **76** and one of the other electrodes. Amplified output signals can be taken thus from between electrodes **72** and **74**. The construction of FIG. 3 is susceptible to breakdown at pinch-off because here, as well as in the Shockley discussion, the space charged region is non-uniform with the junction area. Breakdown additionally may occur rendering the device conducting so that the FIG. 4 construction is limited both in current level, as well as amplification characteristics.

In FIG. 5 is shown an embodiment of the invention constituting an improvement of the unipolar transistor construction shown in FIG. 3. This construction somewhat similar to that of FIG. 3 has a first semiconductive region **81** and a second semiconductive region **82**, the regions having opposite types of conductivity so that a junction exists between them. Output electrodes are illustrated in the form of a central non-rectifying electrode **86** engaging body **81**, and a circular non-rectifying electrode **88** surrounding electrode **86**. Between the two electrodes **86**, **88** is produced an annular depression **85** extending into body **81** in order to increase the amplification effect of the device. The depth of the depression should be such as to approach the junction region, e.g. less than 5 mils therefrom. The use of a rotating etch jet as described in the above-identified patent application, Serial No. 460,835 (abandoned), makes a very convenient technique for the annular cutting operation. A suitable biasing electrode of the non-rectifying type can be provided as indicated, for example, at **84**. Using this technique allows close control of the distance between the junction and bottom of cut.

Of course, it is to be understood that where even higher amplification is desired or where it is desired to increase the useful current ranges of the device, thus requiring complete avoidance of the breakdown in the pinch-off region resulting from the non-uniformity of the space charged region, the construction of FIG. 5 is modified to conform to the concept of FIG. 1. This is readily accomplished by imposing a second annular groove on the opposite surface of the crystal of FIG. 5, namely that surface whereon electrode **84** is shown to be imposed.

Instead of applying the bias to the same electrodes by which the input signals are impressed, other electrodes can be used. In the construction of FIG. 1, for example, bias can be provided between electrodes **18** and **22**, whereas the input signals can be applied between electrodes **20** and **24**. A similar arrangement can be used in the construction of FIG. 2. Furthermore, the bias need not be applied between correspondingly located electrodes, and can be impressed between electrodes **18** and **24**, for example. The incoming signals can also be applied in this manner.

FIG. 6 shows a further form of unipolar transistor construction most useful as a photosensitive device in which the bulk of the crystal **91** is of one conductivity, e.g. n-type, however a diffused junction exists at the region of the depression. In the depression there is an electrode **93**, and at opposite edges of the crystal are non-rectifying electrodes **97**, **98**. The electrode **93** and one of the other non-rectifying electrodes **97** are connected to a high impedance bias source shown as a resistive impedance **96** and a voltage source or battery **95**. When the body **91** of such material is exposed to incident light, current flows across the web between electrode **93** adjacent the irradiation site and the crystal **91**. This current flow reduces the bias imposed by the battery **95** through resistor **96**. Thus the space charge in body **91** adjacent to electrode **93** is reduced allowing greater flow of current in the channel between non-rectifying electrodes **97**, **98**.

The voltage source **95** biases the electrode **97** in the current-blocking direction. With the impedance **96** relatively low as compared to the blocking impedance of the un-illuminated junction, the potential of source **95** is essentially entirely impressed across this junction **94**. When irradiation takes place, the impedance of the junction is sharply diminished so that the potential across the junction **94** is greatly lowered. The lowering of the potential across the blocking junction causes a corresponding amplified change in the current passed between output electrodes **97**, **98** as a result of the decrease of the space charge region. The photoelectric output of the construction of FIG. 6 will accordingly be much higher than that conventionally obtained from present devices, and has a sensitivity to radiation which is remarkable.

Although it is to be fully understood that the following specific examples are representative of the best constructions known to us, they should not in any way limit the scope of the instant invention. Reference should now be made to the drawing of FIG. 1 wherein in its preparation one would take a rectangular slab of p-n junction crystal produced by surface melting techniques or other techniques known to the art, and properly dimension the crystal as follows: The crystal could be a cube of 100 mils in each dimension with the junction region substantially in the center of the plane of the cube. Such a crystal would be of germanium and have for the p-impurity indium and for the n-impurity antimony, with each region of conductivity having a resistivity in the order of 5 ohm-centimeters. As indicated above, such a crystal could be produced by any of the known techniques including the surface melting technique fully disclosed in the copending application of Lehovec et al., Serial No. 364,138, filed June 25, 1953 (abandoned). The depressions **16**, **17** should be then imposed across the opposing faces of the crystal first by magnetostrictive cutting with an appropriate tool, which technique is fully disclosed in United States Patent No. 2,580,716. The width of this cut would be approximately 15 mils and extend with vertical sides down to the region adjacent to the junction. After the magnetostrictive cutting has produced a depression of

Application June 17, 1955, Serial No. 516,180

4 Claims. (Cl. 250—211)

This invention relates to semiconductor signal translating devices and more particularly to bi-stable circuits which include a novel semiconductive device.

Bi-stable circuits that include transistors of the junction type form the subject matter of United States Patent No. 2,655,609, issued October 13, 1953. This patent is concerned with the use of a pair of symmetrical multiple junction transistors associated so as to constitute a composite circuit element having novel advantageous characteristics as a switching structure readily transferable from the open circuit to the closed state upon application of a voltage of prescribed amplitude between the input terminals. The individual transistors used have to be protected carefully against the influence of the operational enviroment by hermetic sealing. This requirement of hermetic sealing necessitates a housing requiring a substantially greater volume than that volume demanded by the physical configuration of the transistor itself. Further, to be satisfactory, the operational characteristics of the two transistors must be carefully matched for incorporation into the circuit.

One general object of this invention is therefore to produce multiple junction semiconductor crystals suitable for bi-stable circuits. A more specific object of this invention is production of a fused junction by a novel process. Other objects will be apparent from the following paragraphs and appended drawings.

Briefly, the objects of this invention have been achieved by the production of a semiconductive crystal of the symmetrical multiple grown junction type which further has at least two fused junction regions integrated into one conductivity region of the multiple junction.

In a more limited sense, the objects of this invention have been achieved by the production of a signal translating device which comprises a semiconductive crystal of the symmetrical multiple grown junction type having at least two fused junctions with electrodes secured respectively to the intermediate section of said multiple grown junction, the two said fused junctions and the end regions of said multiple grown junction.

The invention and the other features noted above will be understood more clearly and fully from the detailed description with reference to the accompanying drawings in which:

Fig. 1 is a cross-sectional view of the grown and fused junction semiconductor element of the invention;

Fig. 2 is a diagram representing a circuit embodiment of utilizing the device of the invention;

Figs. 3, 4 and 5 depict other circuitry including both Zener diodes and the device of the invention;

Fig. 6 illustrates an amplifier circuit using the single transistor of the invention;

Fig. 7 pictures a cross-sectional view of a light responsive signal translating device; and

Fig. 8 is a cross-sectional view of an apparatus for imposing the fused junction regions onto the surface of the multiple grown junction crystal.

Referring now to the drawings, Fig. 1 shows a cross-

2

section of a semiconductive structure which replaces two of the transistors previously required for bi-stable circuits. The crystal 10 is monocrystalline and of germanium or silicon appropriately doped with impurities so as to effect symmertical multiple junctions of the n-p-n or p-n-p types. Herein is shown a grown n-p-n crystal having the n-regions designated 12 and 14 and the p intermediate region as 16. At one end of the crystal there are imposed two regions 18 and 20 of p conductivity produced as fused junctions. It is thus seen that there is in one crystal an n-p-n body which in turn finds one of the regions of n conductivity serving as the intermediate conductivity region for a p-n-p junction crystal. Appropriate non-rectifying electrodes 22, 24, 26, 28 and 30 are attached to the crystal shown in Fig. 1. For best operation the crystal 10 has surface depressions in which the fused junctions are produced so as to limit the thickness of the intermediate n region. For certain applications it is not necessary to have the non-rectifying electrode 26 present.

In Fig. 2 which shows an elementary circuit application of the device of the invention the source 32, poled as shown in the drawing, is connected between the terminals 34 and 36 of the composite crystalline body. The terminals 34 and 36 may be, for example, the cross points in telephone switching systems. The polarity of the source 32 is such that at least one reversed biased junction is included in every current path that can be traced between the terminals 34 and 36 through the composite multiple junction crystal 10. Thus, as shown, the junctions J–2 and J–4 are biased in the reverse or high resistance direction, at least one of which junctions is included in any current path through the combination. The operating state with such a polarity is thus the high impedance or low current condition. Upon increase of the voltage between the terminals 34 and 36 the currents passed by the reversely biased junctions J–2 and J–4 will increase changing the bias across J–1 and J–3 which is a function of the current flow through resistors 38 and 40. At a certain potential the circuit will change to a high current or conduction condition which state obtains when the resistances of the crystal approach those of resistors 38 and 40. Thus the circuit may be triggered from a substantially open circuit (low current) state to a closed circuit (high current) state by the application of voltage of a necessary magnitude between the terminals 34 and 36.

In certain applications it is desirable to determine the point at which the circuit will trigger at a present value. This is readily accomplished by modification of the circuit of Fig. 2 to that of Figs. 3, 4 and 5 by the utilization of a semiconductor junction diode 50, for example, germanium or silicon, which is connected in series with resistor 40 between the terminals 34 and 36. Therefore in Fig. 3, when the voltage between the terminals 34 and 36 rises to such a level as to establish the Zener voltage across the diode, the resulting large current which flows through both resistors 38 and 40 produces such biases on the respective emitters of the composite transistor element to transfer the condition from a low current to a high current level. The preparation of such Zener diodes is readily accomplished by surface melting of a crystal of given impurity, doping the melt with an impurity which produces a body of opposite conductivity and solidifying. The Zener voltage is a function of the conductivity of the crystal and can thus be fabricated for a given voltage of up to 100 volts or greater. In both Figs. 2 and 3, after the device is triggered to the high current or closed circuit conditions, it remains in that condition until the voltage between the terminals 34 and 36 is reduced to substantially 0. For ease of discussion the designation of the elements is common for Figs. 2, 3, 4 and 5. In

MULTIPLE SEMICONDUCTOR ASSEMBLY
Kurt Lehovec, Williamstown, Mass., assignor to Sprague Electric Company, North Adams, Mass., a corporation of Massachusetts
Filed Apr. 22, 1959, Ser. No. 808,249
7 Claims. (Cl. 317—101)

This invention relates to a multiple semiconductor assembly, and more particularly to a plurality of semiconductive devices produced on a single semiconductor slice. Still more particularly, this invention relates to the micro-miniaturization of semiconductor assemblies by the preparation of several transistors and related devices on a single semiconductor slice, and the utilization of the resistive and capacitive properties of regions in that slice.

The present day miniaturization of electronic components has reached a state of art that may now be termed "micro-miniaturization," which may be defined as the assembly of a plurality of complementary components in an extremely small volume. Considerable activity has been expended in micro-miniaturizing circuits in which a plurality of transistors is employed. This micro-miniaturization activity has included the concept of direct coupling between stages of some particular types of transistors; e.g., surface-barrier and alloy-junction transistors have properties that permit their use in so-called common-emitter configurations in which the voltage at the collector of one transistor may be high enough to cause saturation at the base of the next transistor in the circuit. An article entitled, "Directly Coupled Transistor Circuits" by R. H. Beter, W. E. Bradley, R. B. Brown and M. Rubinoff, which was published in Electronics for June 1955, discloses the concept of employing a common-emitter transistor amplifier having more than one base connected to a single collector. Others in the art have suggested processes for producing a plurality of p-n junctions in a single semiconductor body; e.g., G. K. Teal U.S. Patent 2,727,840 and R. N. Hall U.S. Patent 2,822,308. However, great difficulty has been experienced in reaching the objective of a generally acceptable multi-transistor assembly on a single semiconductor body, because transistors so-produced have been electrically connected through the semiconductor slice. For example, in transistors of the alloy-junction type wherein the semiconductor slice of homogeneous impurity concentration represents the base of the transistor, all transistors in a multi-transistor assembly are connected to a common base, which is not a desirable configuration for many circuit applications.

A further example of the restricted nature of prior art multi-transistor assemblies is found in my U. S. Patent 2,779,877 issued January 29, 1957, which discloses and claims a signal translating device comprising a semiconductive crystal of the symmetrical grown junction type having two fused junctions disposed inwardly from opposed surfaces of the crystal.

It is an object of this invention to overcome these and other deficiencies of the prior art.

It is a further object of this invention to produce an assembly having a plurality of semiconductive components on a single semiconductor slice, and to provide a sufficient degree of electrical insulation between these semiconductive components through the semiconductor slice so as to permit a circuit designer to have substantial freedom in the interconnection of the components.

It is a still further object of this invention to produce an assembly having a plurality of transistors together with other components such as capacitors, resistors and diodes on a single semiconductor slice.

These and other objects of this invention will become more apparent upon consideration of the following de-

2

tailed description when read in conjunction with the accompanying drawing, wherein:

FIGURE 1 is a diagrammatic perspective view of a multiple semiconductor assembly constructed in accordance with this invention, with electrical circuit wiring attached thereto to accomplish the circuit shown in FIGURE 3;

FIGURE 2 is a diagrammatic cross-section of the multiple semiconductor assembly taken along line 2—2 in FIGURE 1; in order to establish a clearer picture of the electrical interconnection of the various semiconductive components, FIGURE 2 is not a true cross-section of FIGURE 1, in that the contacts at the front surface of the assembly of FIGURE 1 have been shown again on the diagrammatic cross-section of FIGURE 2, although it should be understood that these contacts are not in the plane 2—2 of FIGURE 1;

FIGURE 3 is a schematic diagram of a chain of direct coupled amplifiers which may be assembled on a single semiconductor slice of the configuration shown in FIGURE 1 in accordance with this invention;

FIGURE 4 is a diagrammatic cross-sectional view through a multiple region semiconducting slice such as may be used in the construction of another embodiment of the multiple semiconductor assemblies according to this invention; and

FIGURE 5 is a diagrammatic plan view of the multiple region semiconductor slice of FIGURE 4.

In general, the objects of this invention are attained by a multiple semiconductor assembly in which a plurality of semiconductor components are prepared on the same semiconductor slice in such a manner as to ensure electrical separation of the terminals of the individual semiconducting components. Since these semiconducting components will be transistors in many cases, the following description will be directed specifically to transistors although the concept of the invention applies also to other components, such as capacitors, resistors and diodes.

More particularly the objects of this invention are attained by utilizing a semiconductor slice having a series of p-n junctions that are so constructed and arranged that a transistor may be produced on each of a plurality of regions that are separated from one another by at least one additional p-n junction.

It is well known that a p-n junction has a high impedance to electric current, particularly if biased in the so-called "blocking direction," or with no bias applied. Therefore, any desired degree of electric insulation between two components assembled on the same slice can be achieved by having a sufficiently large number of p-n junctions in series between the two semiconducting regions on which said components are assembled. For most circuits, one to three p-n junctions will be sufficient to achieve the desired degree of insulation. These p-n junctions may be placed quite closely to each other. However, it is often required that they are placed sufficiently far apart from each other that the multiple p-n junction structure used for electric insulation should not act as an active semiconducting element such as a transistor or a four-layer npnp diode. In order to assure this condition, it is required that the region between two junctions is wider than a small multiple of the diffusion length of the minority carriers in said region. The diffusion length is the square root of the diffusion constant multiplied by the lifetime of these minority carriers. For instance, assuming a diffusion constant of 40 cm.^{2} per second and a lifetime of 1 microsecond, a diffusion length of 60×10^{-4} cm. or approximately 2 mils results, and a separation of 4 mils between the two junctions will be sufficient to avoid any appreciable interaction by carrier injection between the two junctions delineating said region.

In a restricted form of this invention, the objects are attained by a multiple transistor assembly comprising a

Die Störstellenkonzentration ist in der Basiszone eines üblichen Flächentransistors praktisch konstant, so daß dort kein elektrisches Feld herrscht. Die vom Emitter herkommenden Minoritätsladungsträger können also nur durch reine Diffusion zum Kollektor gelangen. Dieser Flächentransistor ist also ein »Diffusions-Transistor«. Die Anwendung desselben ist gegenüber derjenigen des Spitzentransistors durch die wesentlich niedriger liegende Frequenzgrenze beschränkt.

In der Patentanmeldung P 13 01 862.7-33 (deutsche Auslegeschrift 1 301 862) ist bereits ein Verfahren zum Herstellen eines Drifttransistors angegeben, das darin besteht, daß eine oder mehrere Störstellenarten in die Basiszone von der Emitterseite so eindiffundiert werden, daß die Störstellenkonzentration an der Emitterseite der Basiszone mindestens zehnmal größer als an der Kollektorseite der Basiszone ist. Es ist dort auch bereits hervorgehoben, daß es bei einem solchen Drifttransistor besonders vorteilhaft ist, die Störstellenkonzentration vom Emitter zum Kollektor monoton abklingend verlaufen zu lassen, wobei die Abnahme an der Emitterseite stärker ist als an der Kollektorseite, so daß der 2. Differentialquotient der Kurve der Störstellenkonzentration überwiegend positiv ist. Beispielsweise kann die Störstellenkonzentration etwa rein exponentiell abfallen. In der Baziszone herrscht dann wegen der räumlichen Konstanz der Fermischen Grenzenergie ein ungefähr konstantes elektrisches Feld, welches die Minderheitsträger zwangläufig zum Kollektor hintreibt. Dies hat zur Folge, daß die oberste Grenzfrequenz des Transistors ansteigt.

Die Erfindung betrifft einen Drifttransistor, bei dem das elektrische Feld in der Basiszone des Transistors erfindungsgemäß dadurch erzeugt wird, daß die Halbleitergrundsubstanz selbst ein nichtstöchiometrischer Mischkristall verschiedener Halbleitermaterialien mit verschiedenen Bandabständen ist, wobei sich die Zusammensetzung des Mischkristalls innerhalb der Basis derart ändert, daß die Bandbreite von der Emitter- zur Kollektorseite monoton abnimmt, während der Leitfähigkeitstyp unveränderlich bleibt. Auf diese Weise läßt sich ein noch höheres Driftgefälle und damit eine noch stärkere Verbesserung der Frequenzgrenze erzielen.

Gegebenenfalls kann zusätzlich zu der Bandbreitenvariation die Störstellenkonzentration des Halbleitermaterials vom Emitter zum Kollektor monoton abnehmen. Dabei ist zweckmäßig die Feldstärke, die durch das Zusammenwirken von Störstellen- und Bandbreitenvariation entsteht, möglichst homogen zu machen. Diese Maßnahmen können zu einer weiteren Steigerung des Driftgefälles und damit zu einer weiteren Verbesserung der Frequenzgrenze führen. Vorzugsweise verläuft die Variation der Bandbreite linear, während der Störstellengehalt konstant ist oder exponentiell verläuft.

Als miteinander zu kombinierende Halbleitersubstanzen kommen für die Erfindung alle die Halbleitermaterialien in Frage, die auch sonst für die Transistorherstellung geeignet sind, vorausgesetzt, daß die Symmetrie ihrer Kristallgitter dieselbe ist. Dies sind insbesondere die Halbleitersubstanzen der IV. Gruppe des periodischen Systems der Elemente, wie Germanium und Silizium, sowie die gemischten Halbleiter vom Typ $A_{III}B_V$. Und zwar kann man sowohl Halbleitermaterialien der IV. Gruppe untereinander, als auch einen oder mehrere Halbleitermaterialien der IV. Gruppe mit einem oder mehreren $A_{III}B_V$-Halbleitern, als auch mehrere $A_{III}B_V$-Halbleiter untereinander kombinieren.

2

Die Herstellung der erforderlichen dünnen Basisschichten mit inhomogener Zusammensetzung geschieht zweckmäßigerweise so, daß man eine geeignete Menge einer geeigneten flüssigen Mischung der Komponenten langsam von einer Seite her erstarren läßt. Dabei ändert sich die Zusammensetzung des erstarrten Kristalls stetig, beginnend mit der Halbleitersubstanz des höchsten Schmelzpunktes, die im ersten und im dritten Falle der obigen Kombinationsmöglichkeiten gleichzeitig die Halbleitersubstanz mit dem höchsten Bandabstand ist.

Vorzugsweise kann man diesen Schmelzprozeß so durchführen, daß man die niedrigschmelzende(n) Komponente(n) auf ein festes Kristallstück der höchstschmelzenden Komponente aufbringt und das Ganze so hoch erhitzt, daß erstere schmilzt bzw. schmelzen und eine geeignete Menge der letzteren auflöst bzw. auflösen, woraufhin man die Erstarrung wie oben beschrieben durchführt.

Der hochschmelzende Kristall und die niedrigschmelzende(n) Komponente(n) werden dabei zweckmäßigerweise in einander entgegengesetzter Richtung so vordotiert, so daß sich beim Erstarren sogleich der eine der beiden die Basiszone begrenzenden pn-Übergänge bildet.

Wir betrachten jetzt einmal näher den Fall eines nur zweikomponentigen Mischkristalls, wo die höchstschmelzende Komponente auch den höheren Bandabstand hat. Dann bildet der nach dem beschriebenen Verfahren zuerst entstehende pn-Übergang später den Emitter. Es ist dann zweckmäßig, zur Vordotierung des festen Kristalls einen Stoff mit sehr kleinem Verteilungskoeffizienten zu wählen, d. h. einen Stoff, der beim Erstarren bevorzugt in die flüssige Phase geht, während man die niedrigschmelzende Komponente zweckmäßigerweise mit einem Stoff mit einem möglichst großen Verteilungskoeffizienten, vorzugsweise einem Verteilungskoeffizienten > 1, vordotiert. Man erhält dann nämlich gleichzeitig beim Erstarren der Schmelze den gewünschten monotonen Abfall der (Netto-)Störstellenkonzentration. Wenn die Verteilungskoeffizienten der beiden Dotierungsstoffe sich hinreichend stark unterscheiden, überwiegt schließlich gegen Ende des Erstarrungsprozesses wieder die Störstellenart des Emitterkristalls, so daß auch der zweite die Basiszone begrenzende pn-Übergang, der Kollektorübergang, in demselben Vorgang entsteht. Durch Variation der Menge der zweiten Halbleiterkomponente und Variation der Fremdstoffgehalte lassen sich die physikalischen Parameter der so entstehenden Transistoren in weitem Bereich beeinflussen.

Im Falle einer Silizium-Germanium-Kombination eignen sich zur Dotierung des Emitterkristalls vorwiegend die Elemente der III. Gruppe des Periodensystems der Elemente wie Arsen oder Antimon, zur Dotierung des Germanium vorwiegend Bor und Aluminium. Dabei entstehen npn-Transistoren.

Ganz analoge Überlegungen gelten für mehrkomponentige Systeme für andere Halbleiterarten sowie für den Fall, daß die höherschmelzenden Komponenten den niedrigeren Bandabstand haben.

ABSTRACT OF THE DISCLOSURE

A means for controlling the oscillation mode in bulk negative conductivity semiconductor oscillators. By doping the semiconductor so that a resistivity gradient exists between the positive and negative electrodes with a higher resistivity at the positive electrode, the oscillator can be made to reliably function in the pure accumulation mode. If the resistivity gradient is in the opposite direction, operation will be in the dipole space charge mode. Alternatively the operating mode can be controlled by utilizing a negative electrode formed of a semiconductor material having a higher resistivity than the semiconductor material of the main body and having a positive mobility over the operating range of the oscillator device.

This invention relates in general to microwave oscillators utilizing semiconductors which exhibit bulk negative conductivity and more particularly to the use of resistivity gradients and heterojunction electrodes in bulk negative conductivity semiconductors for the purpose of mode control.

The phenomena of bulk negative conductivity (BNC) in semiconductors having a particular type of band structure which results in the semiconductor having a drift velocity v vs. electric field E dependence which contains a region of negative differential mobility $\mu = dv/dE < 0$ or a bulk negative conductivity has finally been achieved. The utilization of BNC semiconductors as oscillators, frequency generators at microwave frequencies up to 100 and perhaps 1000 gc., which is an ultimate limit, is clearly forseeable. The present invention is concerned with basic improvements in such BNC semiconductors with a resultant improvement in efficiency and spectral purity of the microwave oscillations generated by a BNC semiconductor.

The following background information should help in clarifying the terminology involved in the phenomena of a BNC semiconductor and lead to a better understanding of the basic improvements taught by the present invention.

An illustrative graphical portrayal of a typical BNC semiconductor drift velocity v vs. applied electric field E dependence containing a region of bulk negative differential conductivity is shown in FIG. 1. The region between T and V where $\mu = dv/dE < 0$ where μ=electron mobility typifies a BNC semiconductor. The negative differential mobility region occurs at applied electric fields above E_T and extends to E_V. The exact values of E_T and E_V will of course depend on the particular BNC semiconductor under consideration.

The rationale for the negative differential mobility region of the FIG. 1 plot can be seen from an examination of the generic energy band diagram of FIG. 2. This K-space diagram is particularly directed to n-type GaAs but is representative of the generic class of semiconductors falling within the teachings of the present invention. In brief, the conduction band structure of a BNC semiconductor will be a many valley type characterized in the following manner:

2

The semiconductor will be an n-type semiconductor body having a conduction band structure characterized by having satellite valleys which lie energetically higher than a central main valley, with the satellite valleys further characterized by a lower mobility (higher effective mass) than the mobility (lower effective mass) associated with the central main valley, and wherein the energy differential between the bottom of the satellite valleys and the bottom of the central main valley portions of the conduction band is smaller than the energy differential between the top of the valence band and the bottom of the central main valley of the conduction band and wherein the energy differential between the bottom of the satellite valleys and the bottom of the central main valley portion of the conduction band is greater than $2kT$ at the operating temperature where k=Boltzmann's constant and T=absolute temperature in degrees Kelvin of the semiconductor body or crystal temperature at the operating temperature.

It is to be noted that the generic band structure is obviously not to be restricted to any particular crystallographic axis such as the (100) axis which was chosen only to illustrate a particular example of the general case.

This type of semiconductor will, upon application of a D.C. bias voltage such that $V/w > E_T$ for any portion of the body where

V=bias voltage
w=semiconductor body width between source and drain electrodes and
E_T=threshold field;

generate traveling space charge domains which originate at the negative or source electrode and exit at the drain electrode. The exact natural frequency of any given BNC semiconductor will of course vary with the bias, load, material, etc., parameters. The generation of traveling space charge domains can be shown to occur for BNC semiconductor diodes characterized by the following relationship:

$$nw \gtrsim 10^{12}/\text{cm.}^2$$

where n=conduction electron number density and w=semiconductor body width or thickness in cm. between source and drain electrodes.

The generated frequency will in any case be approximately $f \approx 10^7/w$. in Hz. or cycles/sec. with an upper limit around v_T/w and a lower limit around v_L/w at fields above E_T.

The spectral purity, coherence etc. of any given BNC semiconductor oscillator is dependent upon the particular type of traveling space charge domain being generated and the initial starting conditions. The observed rather erratic performance of BNC semiconductors with regard to poor coherence and spectral purity is fundamentally due to microscopic spatial fluctuations in the impurity distribution of the donor ions which results in instabilities in the nature of the initial starting conditions of the traveling space charge domains. By the utilization of resistivity gradients in the main body of the semiconductor between the source and drain electrodes it is possible not only to better control the point of origin of a given space charge domain but also to predetermine the particular type of domain which will be propagated. The resistivity gradients can be positive or negative between the source and drain electrodes and the particular shapes are preferably linear although stepped, non-linear and curved gradients would suffice.

By introducing a positive resistivity gradient between the source and drain electrodes of a BNC semiconductor, higher resistivities at positive or drain electrode, the curve of potential energy of the conduction electrons ϕ along the direction of applied field, just prior to the onset of

(Bundesrepublik Deutschland)

Identifizierungsanordnung mit einer Anzahl frei beweglicher Identifikanden und einem Identifikator

Jürgen Dethloff, Hamburg, und Helmut Gröttrup, München (Bundesrepublik Deutschland), sind als Erfinder genannt worden

1

Die Erfindung betrifft eine Identifizierungsanordnung mit einer Anzahl frei beweglicher Träger von maschinell auswertbaren, diesen Träger kennzeichnenden Informationen, im folgenden Identifikand genannt, und einer Einrichtung, im folgenden Identifikator genannt, zur Auswertung der im Identifikanden gespeicherten Informationen zum Zwecke der automatischen Verarbeitung von mit dem Identifikanden ausgelösten Benutzungshandlungen, wobei der Identifikand zwischen seinen Eingängen und Ausgängen einen Zuordner enthält, dessen Verknüpfungen den Identifikanden kennzeichnen.

Die genannte Aufgabe liegt z. B. bei der Personenidentifizierung vor, um auf Grund dieser Identifikation bestimmte Vorgänge automatisch auszulösen, was von der Werkeingangskontrolle in Betrieben bis zum bargeldlosen Kauf über Automaten reichen kann. Die Identifizierung von Sachen entsteht als Aufgabe z. B. bei dem Durchlauf von Fertigungslosen durch Werkstätten oder bei der Ortsbestimmung von Fahrzeugen.

Gemäss einem früheren Vorschlag werden die Informationen der verschiedenen Identifikanden durch die verschiedenen Verknüpfungen der in den Identifikanden enthaltenen Zuordnerschaltung dargestellt. Der Identifikator weist eine Anzahl von Sendepunkten und Empfangspunkten auf, zwischen denen der Identifikand entsprechend seinen Verknüpfungen Verbindungen herstellt. Das Grundprinzip des Identifikators besteht darin, dass die Sendepunkte mit definierten Impulsströmen über die im Identifikanden enthaltene Verknüpfung auf die Empfangspunkte des Identifikators einwirken und in diesem auf diese Weise den Code des Identifikanden einspeichern. Der Identifikand und der Identifikator

2

besitzen jeweils die gleiche Anzahl, z. B. zehn, räumlich diskreter Empfangs- und Sendestellen.

Mit dieser bekannten Anordnung ist eine Paralleleingabe der abfragenden Impulse aus dem Identifikator und eine Parallelausgabe der Identifizierungsimpulse aus dem Identifikanden in den Identifikator möglich. Das Zuordnungsprinzip ist aber nicht an den Parallelbetrieb und an die räumlich diskreten Sende- und Empfangsstellen gebunden.

Die vorliegende Erfindung besteht nun darin, dass im Identifikator eine Sendeeinrichtung vorgesehen ist, mit deren Hilfe dem Identifikanden nacheinander eine der Anzahl der Zuordnungsstellen des Identifikanden entsprechende Anzahl von Informationen angeboten wird, dass im Identifikanden eine Wähleinrichtung vorhanden ist, die die eintreffenden Informationen der Reihe nach den Eingängen des im Identifikanden enthaltenen Zuordners zuführt, und dass im Identifikanden eine Sendeeinrichtung vorgesehen ist, deren Modulation durch die Ausgänge des Zuordners bestimmt wird und mittels welcher Sendeeinrichtung, die durch den Zuordner bestimmte Modulation direkt oder indirekt an den Identifikator zur Verarbeitung übertragen wird.

Zur Verteilung der Informationen kann beispielsweise im Identifikator ein Taktgeber vorgesehen sein, dessen Impulse die Eingänge des im Identifikanden befindlichen Zuordners nacheinander markieren, wobei jedem Ausgang des Zuordners eine Impulsgruppe mit einer bestimmten Impulszahl zugeordnet ist, so dass die nacheinander auftretenden Impulsgruppen den Code des betreffenden Identifikanden darstellen. Die Impulsgruppen können durch einen Impulsgruppengenerator gewonnen werden, der entsprechend dem markierten

6.5.8 Light Emitting Diodes (LEDs) and Laser Diodes

German-speaking scientists played leading roles in the development of light emitting diodes (LEDs) and laser diodes. LEDs are much more energy-efficient than incandescent and even fluorescent bulbs, so they are now widely used for everything from illuminated video screens to room lighting. Laser diodes are more compact, rugged, and efficient than most other types of lasers, so they are used for everything from optical disc drives to laser pointers. Both LEDs and laser diodes are utilized in different types of bar code scanners.

Bernhard Gudden (German, 1892–1945) and Robert Pohl (German, 1884–1976) developed and demonstrated the first electroluminescent semiconductor devices, the forerunners of LEDs, during the period 1919–1923. They also developed improved photoelectric cells. See pp. 1106 and 2889.

Zoltan Bay (Hungarian, 1900–1992) and György Szigeti (Hungarian, 1905–1978) extended the work of Gudden and Pohl and filed patent applications on true LEDs in 1939, as shown on pp. 1107 and 2890–2894.

Kurt Lehovec (Bohemian/Austrian/Czech, 1918–2012) worked under Bernhard Gudden during World War II, was extensively interrogated by and came to the United States after the war, and filed detailed patent applications on improved LEDs, quite possibly based on wartime work. See Fig. 6.122 and pp. 1097, 2757–2759, and 2895–2910.

John von Neumann (Hungarian, 1903–1957) made a detailed proposal for laser diodes in 1953, which was likely circulated via his many consulting roles in government and industry, and therefore had a broad and profound influence. See p. 1109.

Walter Heywang (German, 1923–2010) filed detailed patent applications on laser diodes in 1958 (pp. 1110 and 2912–2916)

Herbert Kroemer (German, 1928–) invented the drift transistor in 1953, the double-heterostructure laser diode in 1963, and III-V semiconductor heterostructures in 1966. (See pp. 1111 and 2917–2922.) He won the Nobel Prize in Physics in 2000 for his innovations in microelectronics. Professor Tord Claeson of the Royal Swedish Academy of Sciences described Kroemer's contributions [https://www.nobelprize.org/prizes/physics/2000/ceremony-speech/]:

> Early transistors were relatively slow. Semiconductor heterojunctions were proposed as a way of increasing amplification and achieving higher frequencies and power. Such a heterostructure consists of two semiconductors whose atomic structures fit one another well, but which have different electronic properties. A carefully worked out proposal was published in 1957 by Herbert Kroemer. Today, high-speed transistors are found in mobile (cellular) phones and in their base stations, in satellite dishes and links. There they are part of devices that amplify weak signals from outer space or from a faraway mobile telephone without drowning in the noise of the receiver itself.
>
> Semiconductor heterostructures have been at least equally important to the development of photonics—lasers, light emitting diodes, modulators and solar panels, to mention a few examples. The semiconductor laser is based upon the recombination of electrons

> and holes, emitting particles of light, photons. If the density of these photons becomes sufficiently high, they may begin to move in rhythm with each other and form a phase-coherent state, that is, laser light. The first semiconductor lasers had low efficiency and could only shine in short pulses.
>
> Herbert Kroemer and Zhores Alferov suggested in 1963 that the concentration of electrons, holes and photons would become much higher if they were confined to a thin semiconductor layer between two others—a double heterojunction. [...]
>
> Lasers and light emitting diodes (LEDs) have been further developed in many stages. Without the heterostructure laser, today we would not have had optical broadband links, CD players, laser printers, bar code readers, laser pointers and numerous scientific instruments. LEDs are used in displays of all kind, including traffic signals. Perhaps they will entirely replace light bulbs. In recent years, it has been possible to make LEDs and lasers that cover the full visible wavelength range, including blue light.
>
> I have emphasized the technical consequences of these discoveries, since these are easier to explain than the spectacular scientific breakthroughs that they have also led to. Challenging problems and matching resources have led to large-scale basic research. The advanced materials and tools of microelectronics are being used for studies in nanoscience and of quantum effects. Scientific experiments and computations are, of course, highly computerized.
>
> Semiconductor heterostructures can be regarded as laboratories of two-dimensional electron gases. The 1985 and 1998 Nobel Prizes in physics for quantum Hall effects were based on such confined geometries. They can be reduced further to form one-dimensional quantum channels and zero-dimensional quantum dots for future studies.

Other groups produced various types of laser diodes around the same time as Heywang and Kroemer. More archival research is needed to determine whether work in the other laser diode groups was seeded by Heywang's or Kroemer's ideas prior to their formal patent applications, by von Neumann's 1953 proposal, or by other German-speaking work going back to World War II.

Zur lichtelektrischen Leitfähigkeit des Zinnobers.

Von **B. Gudden** und **R. Pohl** in Göttingen.

Mit vier Abbildungen. (Eingegangen am 10. August 1923.)

§ 1. Die lichtelektrische Leitfähigkeit des Zinnobers (HgS) ist 1915 von M. Volmer[1]) gefunden. Über die spektrale Verteilung der Lichtempfindlichkeit liegen drei Veröffentlichungen vor:

I. Gudden und Pohl, ZS. f. Phys. **2**, 361, 1920.
II. H. Rose, ebenda **3**, 174, 1920.
III. Gudden u. Pohl, Phys. ZS. **23**, 417, 1922.

In ihrem allgemeinen Verlauf stimmen die Kurven überein: ein sehr ausgeprägtes Maximum beim Einsatz der optischen Absorptionsbande. Im einzelnen bestehen jedoch Abweichungen, die erheblich außerhalb der Versuchsfehler liegen.

Die Aufklärung dieser Abweichungen bildet den ersten Gegenstand der vorliegenden Mitteilung (§ 2).

Die dabei besprochenen Tatsachen geben gleichzeitig die Erklärung des eigentümlichen Einflusses der elektrischen Feldstärke auf das Bild der spektralen Verteilung: wir hatten die Tatsache gefunden: daß an pulverförmigem Kristallmaterial (auch Phosphoren!) das Hervortreten ausgesprochener Maxima an hohe elektrische Felder geknüpft ist[2]) (§ 3).

Endlich behandeln wir in § 4, inwieweit die Beobachtungen an Zinnober mit der Gültigkeit des Quantenäquivalentgesetzes vereinbar sind.

§ 2. Die unter I und II angeführten spektralen Verteilungen stammen noch aus der Zeit, in der man nichts vom lichtelektrischen Primärstrom wußte. Sie beziehen sich daher auf den gesamten lichtelektrischen Strom, für den bei den gewählten Versuchsbedingungen der Sekundärstrom den wesentlichen Anteil geliefert hat. Reiner Primärstrom liegt erst der Reihe III zugrunde.

Im Fall des reinen Primärstromes hängt die spektrale Verteilung, bezogen auf gleiche absorbierte Lichtenergie, nur vom Gange der optischen Absorption ab. Bezogen auf gleiche auffallende Lichtenergie ist außerdem die Schichtdicke maßgebend. Hingegen sind Lichtintensität und benutzte Spannung für das Bild der spektralen Verteilung ohne Einfluß.

ELECTRIC SOURCE OF LIGHT

Zoltan Bay, Ujpest, and György Szigeti, Budapest, Hungary, assignors to General Electric Company, a corporation of New York

Application November 12, 1940, Serial No. 365,374
In Hungary October 23, 1939

11 Claims. (Cl. 176—1)

The invention relates to an electric source of light of such kind as converts electrical energy in a direct manner into luminous energy, and in which it is not necessary to cause the light-radiating solid body employed for the production of the light to be heated by means of the current to the temperature required for the emission of any thermal radiation, the radiation of light being obtained instead by utilizing, on the basis of a new phenomenon, certain special properties of the light-radiating body.

The electric sources of light employed up to now for the most part utilize the thermal radiation of solid bodies heated by means of electric current; further, increasing use is being made of the luminous phenomena set up during the passage of electric current through gases, and of the phenomenon of so-called fluorescence, which latter, as well known, consists in the fact that certain substances, under the influence of ultraviolet light or of cathode rays, emit visible light.

All these sources of light possess certain drawbacks, the most important among which are the following: With electric incandescent lamps or thermal radiators comprising solid incandescent bodies temperatures around 3000° C. were the highest which it has been possible to reach so as to ensure at the same time a satisfactory term of life. Now at this temperature the colour of the luminous radiation is still very far from the colour of the white light corresponding to the colour of sunlight, seeing that the temperature of the sun is about 6500° C. In addition thereto the luminous efficiency of these lamps is, in view of the present degree of development of technical science, unsatisfactory and thus it is mainly to their simplicity, ease of handling and other practical advantages that the wide use made of them is due. As to lamps based on a discharge through gases or vapours, it is a well-known fact that their characteristic is generally negative, because their terminal voltage diminishes with the increase of the intensity of the current passing through them. In order to compensate the negative characteristic, it is, in case of feeding the lamps from sources of energy of constant voltage as generally employed today, e. g. from mains systems, necessary to connect series resistances, choke-coils, reactive transformers, or condensers in series with the lamps, which fact results in a substantial increase of the first cost of the lighting equipment. Moreover, in case of making use of a series resistance the latter will consume unnecessary current, whilst the employment of a choke-coil or reactive transformer will exert a detrimental influence on the phase conditions of the equipment, and condensers can, for practical reasons, not always be employed. A further drawback is constituted by the fact that the ignition voltage of gas discharge lamps is as a rule substantially higher than their operation voltage and that it is therefore either necessary to make provision for special ignition apparatus, or to keep the operation voltage substantially below the mains voltage, either of which arrangements is disadvantageous from an engineering as well as from an economic point of view. Against these drawbacks, however, must be set the advantage, that with lamps of this kind it is possible to obtain luminous efficiencies which are substantially better than those of incandescent lamps. In case of employing fluorescent light the ultra-violet radiation producing such light is as a rule generated by means of a gas-discharge lamp and thus all the drawbacks enumerated above of the latter present themselves. In case of making use of cathode rays it is as a rule necessary to employ very high voltages, in order to ensure the necessary amount of acceleration of the electrons, which circumstance represents a serious drawback in practice and it is only by means of voltages exceeding 1000 volts, with the aid of complicated apparatus and as a rule with an unsatisfactory term of life that satisfactory luminous efficiencies can be obtained.

In addition to these methods actually employed in practice for the production of light, other methods of producing light by means of electric voltages are also known, which methods, however, have, for the reasons which will be clear from what follows, not found any practical employment for the purposes of lighting technique.

Faint luminous phenomena have already been observed on the carborundum crystals of crystal detectors at the point of contact between the needle and the crystal, where minute luminous points have appeared. This phenomenon was interpreted by its first observer as representing a cold electron discharge, the very high field intensity set up at the apex or at the edges of the crystal being sufficient for releasing electrons from the solid substance, which cause an electric gas discharge in the ambient gas or air.

It is also known that the layer formed in certain cases on the surface of electrically semiconductive bodies, as for instance, on the effective surfaces of dry rectifiers, crystal detectors or condensers of the electrolyte type, will emit

PHOTON MODULATION IN SEMICONDUCTORS

Kurt Lehovec, Williamstown, Mass., assignor to the United States of America as represented by the Secretary of the Army

Application November 18, 1952, Serial No. 321,253

10 Claims. (Cl. 250—7)

This invention relates to novel processes for producing semiconductor translators and methods of controlling such translators to selectively absorb or emit light quanta in accordance with the rate of carrier injection in said semiconductor. More particularly, this invention relates to semiconductor materials which may be prepared to include selective impurity induced regional distortions. These distortions may be attributable to donor, acceptor, and activator inclusions, and as evidenced by lattice defects, stacking disorders, and structural anomalies in the basal lattice planes. Specifically, these regional distortions are selectively controlled so that the carrier charges injected into the semiconductor may cause energy changes therein to either absorb or emit light

2

provide a photo amplifying system of extremely minute size. Another object is the provision of a translating device composed of a semiconductor material which may emit light with high fidelity dependent upon an internal current flow composed of injected carriers. Other and distinct objects will become apparent from the description and claims which follow.

It is well known that the conductivity of an electronic semiconductor can be controlled by certain impurities or lattice defects, such as to be either n-type or p-type. Semiconductors have been made with regions of n-type conductivity and of p-type conductivity, bordering to each other with an interposed boundary or junction, commonly noted as an n-p-barrier between them. In some parts the electric charge or current is carried by electrons and is commonly denoted as n-type or excess conduction, while in other portions the electric current or charge is transmitted by holes (missing electrons) and is commonly denoted as p-type conduction. It is also known that if a voltage of proper polarity is applied across such a boundary, electrons may be driven from the n-part across the boundary and into the p-part and holes driven from the p-part across the boundary and into the n-part. This phenomenon corresponds to a simultaneous injection of minority carriers into each region tending to provide carrier balance or equilibrium.

If these electrons and holes are present simultaneously in particularly given locations within the semiconductor.

DOUBLE MODULATOR UTILIZING PHOTO EMISSIVE MATERIAL

Kurt Lehovec, Williamstown, Mass., assignor to the United States of America as represented by the Secretary of the Army

Application November 18, 1952, Serial No. 321,254

3 Claims. (Cl. 250—210)

This invention relates to semiconductor translators and more particularly to a new type of luminescent semiconductor. Specifically, the invention relates to novel multiplex signal circuits employing semiconductor photon modulation in a manner not heretofore considered possible.

Certain types of photo-emissive and photo-sensitive electrical translators have long been known and used in the art for numerous applications. Examples of these prior art devices include the phosphors such as alkali halides, zinc sulphide and zinc silicate, as both luminescent and photo-sensitive translators. Other examples are the common photo-emissive cells (caesium, etc.), either vacuum or gas-type, photo-voltaic cells such as

2

combination. The theory explaining this operation is fully set forth in said concurrent application.

Another type of a semiconductor light source modulated by an external electric signal and more fully described in said concurrent application consists in passing an external source light beam through a region adjacent to a p-n barrier of a semiconductor, which semiconductor is biased in the forward direction, so that the electrons and holes injected over the p-n barrier modulate the absorption undergone by the light beam in passing through the semiconductor.

The instant invention has for its primary purpose the application of such new light sources in combination with light-sensitive recorders or receivers in such a manner as to permit integration or differentiation between diverse electrical signals.

In one preferred form of the invention a semiconductor light source is arranged to cooperate with a light-sensitive cell in an electrical network whereby the output of the network may represent either, the summation of two values represented by signals in the network, a selected one of such input signals, or a heterodyning signal generator.

A second form of the invention relates to a frequency analyzer.

Another form of the invention is directed to providing novel circuit components for analogue computers.

A still further form of the invention is directed to a

SECTION I

CONSIDER a crystal volume V, in the shape of a cube with the edge L, thought to be repeated with the period L in all (x, y, z) directions. (This is the scheme of F. Bloch, cf. Sh., pp. 129–153. We put Sh.'s $A_x = A_y = A_z$, and write L for these.) Let d be the lattice constant (this is Sh.'s a), then $L = Nd$, $N = 1, 2, \cdots$. (Sh.'s $N_x = N_y = N_z$, we write N for these.) The general crystal-invariant translation of the general point $\vec{r} = (x, y, z)$ $(x, y, z$ are only defined mod $L)$ is $\vec{r} \rightarrow \vec{r} + d\vec{j}$, where $\vec{j} = (j_x, j_y, j_z)$, with $j_x, j_y, j_z = 0, \pm 1, \pm 2, \cdots$, and only defined mod N. (Sh.'s i, j, k are these j_x, j_y, j_z.) We choose the complete set of stationary state wave functions (eigenfunctions) for electrons in the field of this crystal so, that for the state a, i.e., the eigenfunction ψ_a, the crystal-invariant translation $\vec{r} \rightarrow \vec{r} + \vec{d}_j$ merely multiplies ψ_a by a constant factor of absolute value 1, $\Theta(\vec{j})$:

$$\psi_a \rightarrow \Theta(\vec{j})\,\psi_a.$$

Then necessarily

$$\Theta(\vec{j}) = \exp\left(\frac{2\pi i}{N}(\vec{n} \cdot \vec{j})\right)$$

where

$$\vec{n} = (n_x, n_y, n_z)$$

with

$$n_x, n_y, n_z = 0, \pm 1, \pm 2, \cdots,$$

and only defined mod N.

We can also write

$$\Theta(\vec{j}) = \exp\left(\frac{2\pi i}{h}(\vec{P} \cdot d\vec{j})\right)$$

where

$$\vec{P} = \frac{h}{L}\,\vec{n}. \tag{1}$$

$\vec{P}$ is the "crystal-momentum" of the state a.

SECTION II

A Brillouin-Zone B contains precisely 2 (opposite spin) states for each $\vec{P}$, i.e., for each $\vec{j}$. Hence the total number of its states is $2N^3 = 2L^3/d^3$, i.e., $2/d^3$ states per unit volume.

The energy of the state a, E_a, is a function of $\vec{j}$, or equivalently of $\vec{P}$. We write it in the latter form:

$$E_a = F(\vec{P}).$$

The points

$$\text{I:}\quad n_x = n_y = n_z = O(\text{mod } N), \quad \text{i.e.,}$$

$$P_x = P_y = P_z = O\left(\text{mod } \frac{h}{a}\right)$$

and

$$\text{II:}\quad n_x = n_y = n_z = \frac{N}{2}(\text{mod } N)$$

(we assume, for the sake of simplicity, that N is even), i.e.,

$$P_x = P_y = P_z = \frac{h}{2d}\left(\text{mod } \frac{h}{d}\right)$$

are of special significance—E_a assumes its maximum and its minimum at I and at II, respectively, or at II and at I, respectively. We introduce $\vec{n}'$ and $\vec{P}' = (h/L)\,\vec{n}'$, as follows:

$$\text{For I:}\quad \vec{n}' = \vec{n}, \quad \text{i.e.,} \quad \vec{P}' = \vec{P}.$$

$$\text{For II:}\quad \vec{n}' = \vec{n} - \frac{N}{2}(1, 1, 1), \quad \text{i.e.,}$$

$$\vec{P}' = \vec{P} - \frac{h}{2d}(1, 1, 1).$$

At the maximum, i.e., the upper edge of the zone,

$$E_a = V^u = \frac{1}{2m}|\vec{P}'|^2, \tag{2}$$

at the minimum, i.e., the lower edge of the zone,

$$E_a = V^e = \frac{1}{2m}|\vec{P}'|^2. \tag{3}$$

Here m is the equivalent mass of the hole or the electron, respectively, but it is actually adequately approximated for our present purposes by the mass of the electron (Sh., pp. 176–182, 398).

Figure 6.123: John von Neumann made a detailed proposal for laser diodes in 1953, which was likely circulated via his many consulting roles in government and industry [*IEEE Journal of Quantum Electronics* 23:6:659–673 (1987)].

SEMICONDUCTOR MASER WITH MODULATING MEANS
Walter Heywang, Munich, Germany, assignor to Siemens und Halske Aktiengesellschaft, Berlin and Munich, a corporation of Germany
Filed Apr. 22, 1959, Ser. No. 808,255
Claims priority, application Germany Apr. 30, 1958
16 Claims. (Cl. 332—52)

This invention relates to the control of very high frequency radiation and is particularly concerned with producing or amplifying very high frequency radiation according to the principle of microwave amplification by stimulated emission of radiation briefly referred to as "Maser" principle.

Arrangements operating in accordance with this principle make use of the fact that, when a particle, for example, an electron, is by radiation stimulated to pass from a term of higher energy content to a term of lower energy content, a radiation will be transmitted which corresponds to the energy difference of both terms, such radiation being often stronger than the stimulating radiation, the frequencies of the transmitted and of the stimulating radiation being the same.

Continuous transmission of radiation may be obtained by an auxiliary radiation which is in turn effective to cause particles to pass from the term of lower energy content to a term with an energy content exceeding that of the term from which the particles due to the stimulating radiation pass again into the lower energy content.

The various objects and features of the invention will appear in the course of the description which will be rendered below with reference to the accompanying drawing. In the drawing,

FIG. 1 shows an example of the manner in which a continuous transmission of radiation may be effected;

FIGS. 2*a* and 2*b* illustrate an embodiment of the invention; and

FIGS. 3, 4 and 5 show further embodiments of the invention.

Referring now to FIG. 1, showing in schematic representation the manner of effecting continuous transmission of radiation, terms *a*, *b*, *c* are indicated by short horizontal lines, the energy content of these terms decreasing from the top downwardly. The term *a* accordingly corresponds to an energy content greater than that of *b*, and *b* has an energy content exceeding that of *c*. In this arrangement, a particle (electron) is by auxiliary radiation lifted from the term *c* to the term *a* (see arrow 1), such electron thereupon dropping to the term *b* (see arrow 2), where it adheres. The stimulating radiation, which corresponds to the energy spacing between the terms *b* and *c*, thereupon causes this electron to pass from *b* to *c* (see arrow 3), thereby effecting transmission of amplified radiation the frequency of which as well as that of the stimulating radiation corresponds to the energy spacing E_{bc} between the term *b* and *c*, according to the known formula $E_{bc}=h\cdot\nu$, wherein h is Plank's constant and ν the frequency. Additional information with respect thereto may be found in the book entitled "Introduction to Solid State Physics," by Charles Kittel (University of California), published 1956 by Wiley, New York, page 122. The fact that the lifting of the electron on its path from *c* to *a* requires a greater energy than is liberated upon passage from *b* to *c*, shows that the auxiliary radiation for the lifting of the electron must have greater power than the radiation transmitted upon passage of the electron from *b* to *c*. However, the fact that the frequency of the auxiliary radiation by which the electron is lifted from *c* to *a* must be in accordance with the equation $\nu_{ca}\cdot h=E_{ca}$ higher than that of the transmitted radiation, is in such an arrangement more disturbing. The advantage of continuous transmission of a high frequency radiation is accordingly obtained at the expense of the serious drawback of having to provide for an auxiliary radiation which must not only have very high power but also a higher frequency.

2

The invention avoids these disadvantages in most surprisingly simple manner by providing an arrangement for amplifying very high frequency radiation according to the Maser principle, comprising (*a*) an electron-conducting, particularly a mono-crystalline semi-conductor body having two mutually different regions in which the charge carriers have upon current flow through the semiconductor body different energy content, and in whose transition or junction area between these two regions the charge carriers of higher energy can be responsive to stimulation with high frequency radiation give off an amplified energy radiation of the same frequency; (*b*) a voltage source for effecting flow of charge carriers from the region of higher energy to the transition area; and (*c*) a radiation source the high frequency radiation of which permeates at least into the transition area of the semiconductor body.

The advantage resulting from the above noted features is that electrons of higher energy are by the voltage source continuously introduced into the transition zone between the two partial areas of the semiconductor body, these areas, under the influence of the stimulation radiation entering into the transition zone, passing to lower energy stages while giving off the amplified radiation, for example, recombining with positive charge carriers, and that maintenance of the radiation merely requires continuous current flow through the semiconductor body. The voltage placed on the semiconductor body is preferably a direct current voltage; however, for the modulation of the high frequency radiation transmitted from the semiconductor body, it may preferably fluctuate in the rhythm of the desired modulation frequency. Impulsewise transmission of radiation may be effected by placing on the semiconductor body which is continuously irradiated by a weak stimulation radiation, an alternating voltage or voltage impulses to provide in this manner for the transmission of high frequency radiation impulses.

Basic semiconductor materials very well adapted for arrangements according to the invention include known substances adapted for diodes and transistors, for example, silicon, germanium, $A^{III}B^{V}$-compounds and, in addition other semiconductor substances, for example, bismuthtellurid (Bi_2Te_3). The latter substance is particularly well adapted for purposes of the invention since it exhibits only a slight spacing between the valency band and the line band and having relative to the first mentioned substances only a slight heat conductivity, thereby further favoring the Maser effect.

In order to obtain in the semiconductor body regions of different energy content of the charge carriers, it will be advisable to use a semiconductor body having a p-zone and an n-zone. However, since the frequency of the stimulation radiation and the frequency of the transmitted radiation are, as noted before, in a fixed relationship to the energy loss suffered by the electron, stimulated by the permeating radiation, upon transition of the electron into the term of lower energy content, and since this frequency corresponds in the case of germanium or silicon to a wavelength of about 1 μm, it is for obtaining long wave radiation advisable to provide traps in the transition region between the two p- and n-zones. As explained in the book of Kittel, page 515, first paragraph, traps are impurity atoms or other imperfections in the crystal, the energy level of which may be at times occupied by electrons or holes. Traps are produced as impurities, for example, in silicon or germanium, by the building-in of nickel-, iron- and/or copper atoms. The energy spacing

SOLID STATE RADIATION EMITTERS
Herbert Kroemer, Sunnyvale, Calif., assignor to Varian Associates, Palo Alto, Calif., a corporation of California
Filed Aug. 16, 1963, Ser. No. 302,647
20 Claims. (Cl. 313—108)

This invention relates to solid state radiation emitters, and in particular to novel and improved semiconductor devices that afford enhanced radiating characteristics.

Although the semiconductor device of this invention may be useful for various applications, the description will be directed to the use of the inventive device as a laser, for the purpose of description and explanation. It should be understood that the inventive concept is not limited to laser applications only.

Radiation or lasing action by semiconductors may be achieved in one way by the recombination of injected excess charge carriers. By exciting or stimulating certain semiconductors by means of light energy or electric current, these semiconductors will emit visible light, infrared, or other radiation.

However, radiating or lasing structures utilizing solid state devices have been limited to the direct gap type semiconductors, such as gallium arsenide, indium arsenide and indium phosphide, and to the semiconductor alloys $GaAs_xP_{1-x}$ and $Ga_xIn_{1-x}As$. It has not been possible to effect highly radiative recombination with the common semiconductors of the indirect energy gap type, such as Ge, Si, GaP for example, because a very high carrier injection level is required. The indirect gap type semiconductor is characterized in that an electron from the lowest energy state in the conduction band is not able to recombine radiatively with a hole in the highest energy state in the valence band. In order for the higher electron states to contain any electrons, it is necessary that very high carrier densities be injected, whereby the indirect gap semiconductors will be capable of emitting light by means of recombination.

Also, the presently known semiconductor radiation emitters or lasers are of the homojunction type, that is, the two sides of the PN junction are formed from a single semiconductor material. A homojunction structure cannot inject a higher carrier density than the doping density on the more heavily doped side of the semiconductor junction, and therefore, it is not possible to realize carrier densities or injection levels that are high enough to overcome the degeneracy threshold of the semiconductor, nor the even higher carrier densities needed to cause lasing in indirect gap semiconductors.

The degeneracy threshold may be defined as the injection level above which injected electrons fill more than half of the available electron states at the lower edge of the conduction band, and above which more than half of the electron states at the upper edge of the valence is empty, or filled with holes. The value of the degeneracy threshold varies with the semiconductor material being used. At room temperature, this value may be approximately 10^{18} carriers per cubic centimeter, by way of example. However, the degeneracy threshold decreases with a decrease in temperature, being approximately proportional to $T^{+3/2}$, where T is the absolute temperature. To achieve optimum efficiency, it is preferable to utilize an injected carrier density that is close to the degeneracy threshold. Furthermore, to accomplish coherent light emission, it is necessary that the injected carrier density

2

be greater than the degeneracy threshold. Since only limited injection levels are possible with conventional PN junctions, such as found in the presently known semiconductor lasers, the degeneracy threshold must be lowered by extreme cooling of the structure to provide a suitable injection level.

Thus it is obvious that if high injection densities were provided, there would be no need for the extreme cooling of semiconductor lasers down to cryogenic temperatures. Also, if high injection densities were provided, indirect gap type as well as direct gap type semiconductors could be made to radiate or lase coherently, and at ambient or room temperatures.

Furthermore, with presently known semiconductor lasers having homojunctions, the light is radiated from the end of the junction in a direction substantially perpendicular to the current flow. It would be desirable, as an alternative, to obtain coherent light that is emitted transversely relative to the junction surface of the lasing body and in the direction of current flow so that the light emission covers a substantially wide area.

An object of this invention is to provide novel and improved solid state radiation emitters.

Another object of this invention is to provide high density injection light-emitting structures characterized by increased operating efficiency.

Another object is to provide solid state light emitters and lasers that can operate at ambient temperatures.

A further object is to provide coherent laser devices that afford wide area emission.

According to this invention, a solid state radiation emitter device comprises a semiconductor base, and means for injecting charge carriers of high density into such base and for preventing the outflow of the injected carriers from the base, so that the charge carriers may be efficiently utilized in a radiative recombination process.

In one embodiment of the invention, a solid state radiation emitter includes a thin base or support formed from a first semiconductor material having a relatively low energy gap, and injector electrodes formed from another semiconductor material disposed on each side of such base to form heterojunctions. The injector electrode material is heavily doped and has a substantially wider energy gap than the base material. The pair of wider energy gap injector electrodes are preferably of opposite polarity, one being P-type and the other N-type. An external source of power such as direct electric current, is coupled to the injector electrodes for supplying a forward bias voltage to the emitter device. Thus, excess charge carriers may be injected with a high density so that the degeneracy threshold of the base material is overcome at ambient or room temperatures with resultant emission of radiation. In this manner, a highly efficient light-emitting action is obtained by recombination radiation with indirect gap type semiconductors as well as with direct gap semiconductors at ambient temperatures.

In another embodiment of the invention, the injector electrodes are doped to have the same polarity, and suitable biasing means are coupled to the injector electrodes and to the base to provide high density carrier injection to the base.

In specific embodiments of the invention, reflective or opaque conducting electrodes are disposed on the emitter device so that radiation is directed in predetermined configurations and directions.

It is recognized that various configurations are possible within the scope of the invention whereby injector elec-

Herbert Kroemer (1928–) invented double-heterostructure laser diodes (1963 or earlier)

3,309,553

3

trodes formed from a semiconductor material with a higher energy gap are disposed adjacent to a semiconductor base with a relatively lower energy gap, and energizing means are provided for actuating injection of high density charge carriers into the base. The injector electrodes are so located relative to the base that carrier outflow from the base and surface recombination are prevented.

The invention will be described in greater detail with reference to the drawing in which:

FIGURE 1 is a representational schematic diagram of a semiconductor laser, in accordance with this invention;

FIGURES 2 and 3 are isometric views, partly broken away, of embodiments of this invention;

FIGURES 4 and 5 are isometric views of alternative embodiments of the inventive structure;

FIGURE 6 is a sectional view of another alternative embodiment; and

FIGURES 7–9 are representational schematic diagrams of other embodiments of the invention.

Similar numerals refer to similar parts throughout the drawing. It is to be noted that the figures of the drawing are merely illustrative, and that the parts are not represented in exact proportion.

In the schematic diagram of FIGURE 1, a semiconductor radiation emitter structure, according to this invention, comprises a weakly doped base **10** formed from a lower energy gap material; a higher energy gap P-type injector electrode **12** on one surface of the base; and a higher energy gap N-type injector electrode **14** disposed on the opposite surface of the base **10**. A direct current source **16** supplies a positive potential to the P-type injector electrode **12**, whereas a negative potential is supplied to the N-type injector electrode **14**.

In one embodiment of the invention, the lasing base **10** is formed from a single crystal germanium (Ge) wafer, and the injector electrodes **12** and **14** are made from gallium arsenide (GaAs) that has been suitably doped. The junctions formed between the dissimilar materials are referred to as heterojunctions, in contrast to homojunctions. When manufacturing the inventive laser utilizing these particular materials, a pair of layers of GaAs are grown on a germanium wafer or base having a thickness of about 100 microns or less.

The GaAs layers are formed by first preparing a melt consisting of gallium with a small percentage of arsenic. The arsenic content in the melt depends on the growing temperature, which may range from 350° to 750° C. by way of example. At a growing temperature of 500° C., a mixture comprising approximately 5 atomic percent of arsenic is used. The prepared melt is slowly heated to about 600° C. so that the arsenic reacts with the gallium to form GaAs. (Alternatively, an appropriate amount of GaAs may be dissolved in gallium to provide a suitable mixture.) In order to dissolve the residual arsenic that has not reacted, the melt is stirred repeatedly for the first ten minutes of the slow heating process. When the melt reaches about 600° C., the temperature is maintained for at least ten minutes to allow the excess arsenic to be evaporated, and to remove any condensation nuclei. The temperature of the melt is then reduced rapidly by about 100° C., within a period of less than ten minutes. When the temperature of the melt approaches approximately 500° C., the Ge wafer is quickly immersed into the supercooled melt.

The wafer acts as a seed so that the GaAs grows on the wafer support epitaxially. Before immersion, the Ge wafer is heated to a temperature higher than the melt, i.e. over 600° C., for example. The wafer is left in the melt for at least one minute and then withdrawn, providing a GaAs layer that is about 5–20 microns thick, for example. The above steps are performed in a reducing atmosphere, such as in pure hydrogen.

It is known that commercial arsenic contains impurities which produce only N-type GaAs injector electrodes. To

4

increase the intensity of the N-type doping whereby higher injection levels are realized, an N-type dopant such as tin is added to the melt in a 1% proportion relative to the mixture.

However, in order to obtain a highly efficient semiconductor laser, one of the two GaAs layers is preferably made as a P-type injector electrode **12** by diffusing a P-type dopant such as zinc therein. To introduce the Zn into the GaAs layer, the base wafer and Zn doping material are heated within an evacuated quartz ampoule at about 800° C. for about one hour. The Zn dopant may comprise an alloy of 90% indium and 10% zinc, where the zinc is the primary diffusant and the indium acts as a buffer to prevent excess Zn vapor pressure. In order to retain the N-type doping of the other GaAs injector electrode, the N-type layer is masked with a film of evaporated or vapor-deposited SiO_2 prior to the introduction of the Zn dopant. The Zn diffuses rapidly in the exposed GaAs layer, but relatively slowly in the Ge wafer, and the diffusion virtually stops at the Ge-GaAs junction interface. After diffusion, the SiO_2 masking film is removed from the N-type layer with hydrochloric acid.

An alternative method of forming the semiconductor laser structure, with opposite polarity injector electrodes disposed on each side of a lasing base, employs a pair of Ge wafers that are placed back-to-back in a GaAs solution. N-type GaAs is grown on the exposed side of each wafer, while the surfaces that are positioned closely adjacent to each other are maintained unwetted. The edge surfaces also remain unwetted by coating the wafer edges with colloidal graphite. After growing suitable N-type injector electrodes, the wafers are then placed in a second GaAs solution that has been made P-type by adding one percent Zn, with the two coated N-type grown layers closely adjacent to each other in a back-to-back position. The P-type injector electrodes are then grown, and the graphite coating is subsequently removed from the edges of the two wafers. It is recognized that laser structure with injector electrodes may be produced by vapor epitaxy techniques.

After growing the injector electrode layers of opposite polarity, the structures are cut or cleaved to a desired shape or size, such as illustrated in FIGURES 2–6. Suitable conducting electrodes **18** and **20** are formed on the injector electrodes by evaporation, plating or other known means in any desired configuration, using screening or masking techniques. The electrodes may be formed by brushing or spraying silver paint or by evaporating thin conducting films, such as tin chloride or gold, in a well-known manner. The conducting electrodes may be made opaque or light-transmitting; or may be formed as a combination of opaque and transparent areas to allow selective areal transmission of light.

Various structures incorporating the inventive combination are shown in FIGURES 2–6. With reference to FIGURE 2, an embodiment of the invention includes a disk-like base structure **10** (shown in part) sandwiched between a P-type injector electrode **12** and N-type injector electrode **14**. Annular conducting electrodes **18** and **20**, which may be formed from silver paint, are disposed on the injector electrodes **12** and **14** respectively, and are connected to the terminals of a direct current supply **16**. Upon application of D.C. current, for example 1.0 volt, radiation or light is transmitted transversely to the plane of the base disk **10**. It is understood that the diameter of the base **10** may be of such length that the radiation is emitted radially from the base **10**.

FIGURE 3 illustrates a laser structure similar to that of FIGURE 2, but provides a continuous conducting electrode **22** covering the entire surface of the N-type injector electrode **14**. A reflecting layer **24**, formed from aluminum, for example, that has been positioned between the N-type injector layer **14** and the conductive electrode **22** serves to reflect the light radiation towards the P-type

Figure 6.125: Herbert Kroemer invented the double-heterostructure laser diode in 1963 or earlier.

6.5.9 Superconductivity

As illustrated in Figs. 6.126–6.131, creators from the German-speaking world also dominated research on superconductivity, the elimination of electrical resistance (and thus the elimination of power losses) when conductive materials are sufficiently cold.

Heike Kamerlingh Onnes (Dutch, educated in Germany, 1853–1926) produced the first liquid helium in 1908. By immersing metals in the liquid helium and measuring their electrical properties, he discovered superconductivity in 1911 (Fig. 6.126). He won the Nobel Prize in Physics in 1913 for all of his research on cryogenics—see p. 921 for more information.

Max von Laue (German, 1879–1960), Fritz Walther Meissner (German, 1882–1974), and Robert Ochsenfeld (German, 1901–1993) further studied the properties of superconductors (Fig. 6.127). Max von Laue won the Nobel Prize in Physics in 1914 for some of his other research (p. 668). In 1933, Meissner and Ochsenfeld discovered the now widely known Meissner (or Meissner-Ochsenfeld) effect, the levitation of a magnet above a superconductor; magnetic fields cannot penetrate a superconductor, so the compressed field between a magnet and a superconductor acts as a cushion.

From the late 1920s onward, Kurt Mendelssohn (German, 1906–1980) also extensively studied superconductivity, including the effects of lattice imperfections on superconductivity in various metal alloys. He studied superfluidity, the unusual behavior of fluids at cryogenic temperatures, as well, and he found direct analogies between the electrical behavior of superconductors and the mechanical behavior of superfluids.

In 1935, the brothers Fritz London (German, 1900–1954) and Heinz London (German, 1907–1970) developed the London equations, which provided a theoretical derivation and explanation for the Meissner effect and some other electromagnetic behaviors of superconductors.

Many of those experts on superconductivity fled Germany before World War II and spread their knowledge to other countries, but U.S. and U.K. reports also described impressive work on superconductivity that was carried out by other scientists in Germany and Austria during the war. For example, BIOS 1751, *German Research on Semi-Conductors, Metal Rectifiers, Detectors and Photocells*, gave some insight into one of Rudolf Hilsch's later projects [BIOS 1751]:

> Super-Conductivity[...] Hilsch [...] has investigated the critical temperature ("Sprungpunkt") of various pure metals, (i.e. that temperature at which super-conduction sets in), also the influence of a magnetic field (which has the effect of lowering the critical temperature) and the critical current ("Grenzstrom") which sets up a magnetic field of such magnitude as just to balance the external field. He also studied the very pronounced effects which some metals have on the critical temperature even if added in very small amounts only.

According to official histories, in 1956 the American Leon Cooper first proposed a detailed explanation of superconductivity, focusing on what came to be known as "Cooper pairs" of electrons that work together to avoid electrical resistance. Cooper won the Nobel Prize in Physics for that explanation. The document on pp. 1116–1118 proves that Josef Schintlmeister (Austrian, 1908–1971) and his coworkers had a detailed understanding of this physics no later than 1945, and were forced to give written reports on that to the United States. Scholars should investigate in much more detail the superconductivity research that Schintlmeister and his coworkers carried out, and how information on their discoveries may have influenced later researchers such as Cooper.

Beilage 3

Eine neue Modellvorstellung von der Supraleitung

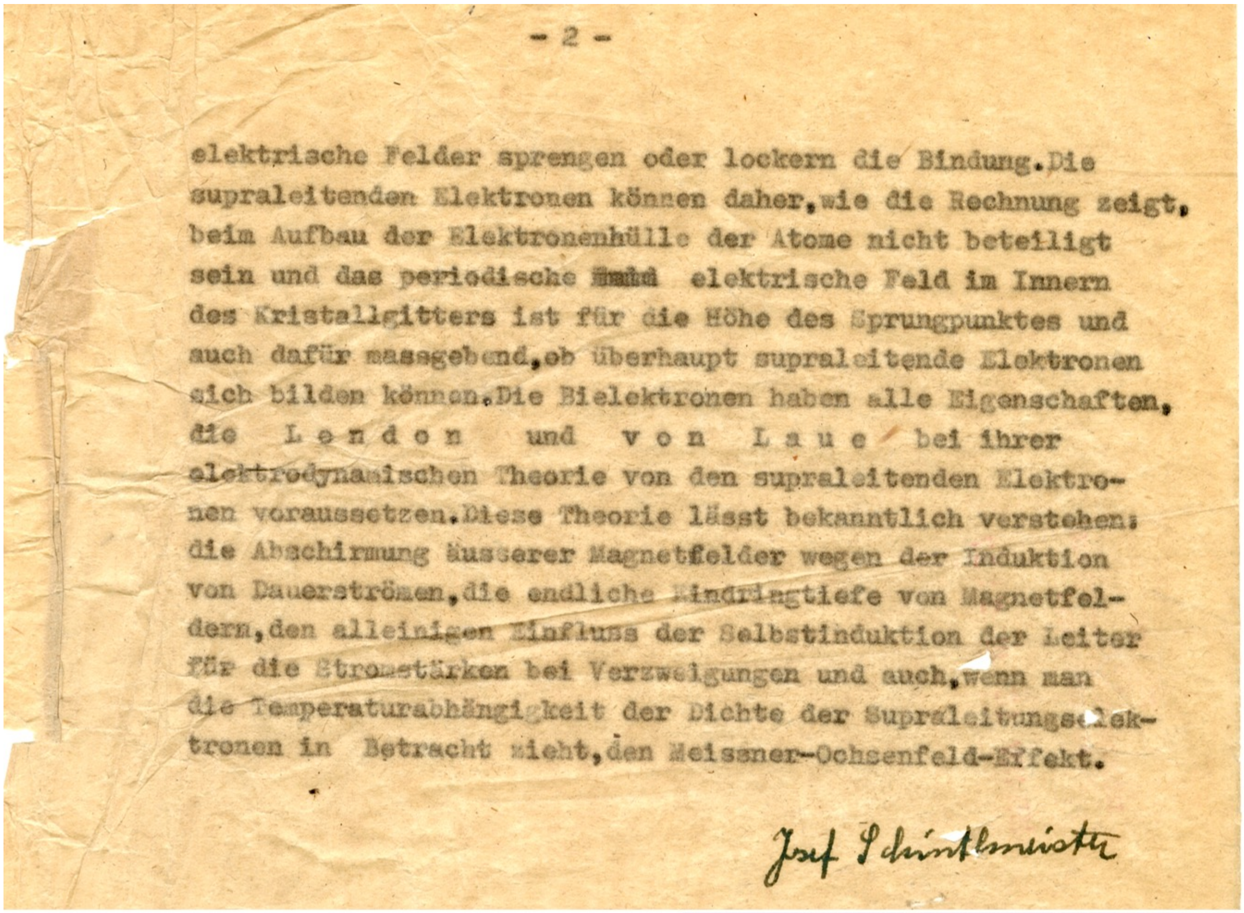
von

Josef Schintlmeister

Zusammenfassung.

Ausgangspunkt der Theorie ist die Vorstellung, dass die supraleitenden Elektronen nicht die Fermistatistik sondern die Bosestatistik befolgen und damit praktisch eine Maxwellsche Geschwindigkeitsverteilung besitzen. Bei der Bildung der supraleitenden Elektronen vereinigen sich gelegentlich eines Dreierstosses zwei Elektronen mit antiparallel gestellten Spinrichtungen unter wellenmechanischer, leicht berechenbarer Durchdringung des Potentialberges zu einem sehr locker gebundenen "Bielektron". Die Bindung ist möglich, da schon in einer Entfernung von etwa dem 5o-fachen klassischen Elektronenradius die magnetische Anziehung die Coulombsche Abstossung überwiegt. Analog der thermischen Dissoziation zweiatomiger Gase lässt sich die Temperaturabhängigkeit der Zahl der supraleitenden Elektronen berechnen. Die bei dem Statistikwechsel freiwerdende Nullpunktsenergie der Elektronen mit Fermistatistik ist Ursache der Zunahme der spezifischen Wärme im supraleitenden Zustand; aus ihr kann in Übereinstimmung mit dieser Rechnung die jeweilige Zahl der supraleitenden Elektronen bestimmt werden. Das Verschwinden sämtlicher Komponenten des elektrischen Widerstandes(Restwiderstand, Kontaktwiderstand, thermischer Anteil des Widerstandes) erklärt sich aus der wegen der geringen Nullpunktsenergie erheblich grösseren Elektronenwellenlänge der supraleitenden Elektronen. Ein genügend starkes Magnetfeld richtet die magnetischen Momente parallel und sprengt damit die Bindung. Für die magnetisch unempfindlichsten Supraleiter(z.B. PbBi, PbHg) ist in Übereinstimmung damit die aufzuwendende magnetische Energie beim absoluten Nullpunkt gleich der thermischen Energie kT beim Sprungpunkt. Auch genügend inhomogene

Figure 6.129: Josef Schintlmeister developed a correct theory of superconductivity, later known as Cooper pairs of electrons, no later than 1945 [G-345, Deutsches Museum FA 002/0712; English translation in FIAT 63].



- 2 -

elektrische Felder sprengen oder lockern die Bindung. Die supraleitenden Elektronen können daher, wie die Rechnung zeigt, beim Aufbau der Elektronenhülle der Atome nicht beteiligt sein und das periodische elektrische Feld im Innern des Kristallgitters ist für die Höhe des Sprungpunktes und auch dafür massgebend, ob überhaupt supraleitende Elektronen sich bilden können. Die Bielektronen haben alle Eigenschaften, die Lendon und von Laue bei ihrer elektrodynamischen Theorie von den supraleitenden Elektronen voraussetzen. Diese Theorie lässt bekanntlich verstehen: die Abschirmung äusserer Magnetfelder wegen der Induktion von Dauerströmen, die endliche Eindringtiefe von Magnetfeldern, den alleinigen Einfluss der Selbstinduktion der Leiter für die Stromstärken bei Verzweigungen und auch, wenn man die Temperaturabhängigkeit der Dichte der Supraleitungselektronen in Betracht zieht, den Meissner-Ochsenfeld-Effekt.

Supplement 3.

Idea for a New Model for Super-Conductivity

by

Josef Schintlmeister

Point of departure of the theory is the idea that the super-conducting electrons do not follow the Fermi statistics but follow Bose statistics and thereby for practical purposes it possesses the Maxwell velocity distribution. Two electrons unite during the forming of the super-conducting electrons when activated by a force in all three directions with easily-computed quantum-mechanical penetration of the potential barrier to a very loosely bound "bielectron". The binding is possible, since the magnetic attraction surpasses the Coulomb repulsion as early as a distance of 50-fold, classical electron-radii. Similar to the thermic disassociation of two-atomic gases, the temperature dependence of the number of super-conducting electrons can be reckoned. The zero energy point of the electrons which become free at the change of statistics with Fermi statistics is the cause of the increase of the specific heat in the super-conducting state; from this the momentary number of the super-conducting electrons can be determined in agreement with this computation. The disappearance of all the components of the electrical resistance (residual resistance, contact resistance, thermic part of resistance) is explained by the considerably larger electron wave-length of the super-conducting electrons; the electron wave-lengths are considerably larger due to the low zero-energy point. A sufficiently strong magnetic field directs the magnetic moment and thus destroys the binding. For the magnetically insensitive superconductors (e.g., PbBl, PbHg), the magnetic energy to be used at the absolute zero-point is equal to the thermic energy kT at the elastic point. Sufficiently inhomogenous electrical fields destroy or loosen the binding. Thus the super-conducting electrons cannot take part in the construction of the electron orbit of the atoms and the periodic, electrical field in the interior of the crystal lattice is decisive for the height of the elastic point and also decisive for the contingency of whether super-conducting electrons can be formed or not. The bielectrons have all the properties which were pre-supposed in the electrodynamic theory of super-conducting electrons by London and von Laue. This theory makes very obvious: the screening of external magnetic penetration of magnetic fields due to the induction of the permanent current, the finite depth-penetration of magnetic fields, the individual influence of the self-induction of the conductors for the current strengths in the branchings and also, if one takes into consideration the temperature dependence of the density of the super-conductor electrons and the Meissner-Ochsenfeld Effect.

To complete the discussion of superconductivity, it should also be mentioned that K. Alex Müller (Swiss, 1927–) and his student Johannes Georg Bednorz (German, 1950–) developed the first high-temperature ceramic superconductors, for which they won the Nobel Prize in Physics in 1987. Professor Gösta Ekspong of the Royal Academy of Sciences explained the importance of their work [https://www.nobelprize.org/prizes/physics/1987/ceremony-speech/]:

> The Nobel Prize for Physics has been awarded to Dr. Georg Bednorz and Professor Dr. Alex Müller by the Royal Swedish Academy of Sciences "for their important breakthrough in the discovery of superconductivity in ceramic materials". This discovery is quite recent—less than two years old—but it has already stimulated research and development throughout the world to an unprecedented extent. The discovery made by this year's laureates concerns the transport of electricity without any resistance whatsoever and also the expulsion of magnetic flux from superconductors. [...]
>
> Dr. Bednorz and Professor Müller started some years ago a search for superconductivity in materials other than the usual alloys. Their new approach met with success early last year, when they found a sudden drop towards zero resistance in a ceramic material consisting of lanthanum-barium-copper oxide. Sensationally, the boundary temperature was 50 % higher than ever before, as measured from absolute zero. The expulsion of magnetic flux, which is a sure mark of superconductivity, was shown to occur in a following publication.

Also for completeness, two other postwar discoveries in cryogenic electrical properties should be mentioned.

Klaus von Klitzing (German, 1943–, Fig. 6.131) discovered the quantum Hall effect, in which the electrical conductivity at the surface of a cryogenic semiconductor in a strong magnetic field can only assume integer multiples of a certain value. He won the Nobel Prize in Physics in 1985. Professor Stig Lundqvist of the Royal Swedish Academy of Sciences praised von Klitzing's discovery [https://www.nobelprize.org/prizes/physics/1985/ceremony-speech/]:

> von Klitzing studied the Hall effect under quite extreme conditions. He used an extremely high magnetic field and cooled his samples to just a couple of degrees above the absolute zero point of temperature. Instead of the regular change one would expect, he found some very characteristic steps with plateaus in the conductivity. The values at these plateaus can with extremely high accuracy be expressed as an integer times a simple expression that just depends of two fundamental constants: the electric elementary charge and Planck's constant which appear everywhere in quantum physics.
>
> The result represents a quantization of the Hall effect—a completely unexpected effect. The accuracy in his results was about one part in ten million, which would correspond to measuring the distance between Stockholm and von Klitzing's home station Stuttgart with an accuracy of a few centimeters. The discovery of the quantized Hall effect is a beautiful example of the close interrelation between the highly advanced technology in the semiconductor industry and fundamental research in physics. The samples used by von Klitzing were relined versions of a kind of transistor we have in our radios. His samples, however, had to satisfy extremely high standards of perfection and could only be made by using a highly advanced technique and refined technology. [...]

> von Klitzing's discovery of the quantized Hall effect attracted immediately an enormous interest. Because of the extremely high accuracy the effect can be used to define an international standard for electric resistance. The metrological possibilities are of great importance and have been subject to detailed studies at many laboratories all over the world.
>
> The quantized Hall effect is one of the few examples, where quantum effects can be studied in ordinary macroscopic measurements. The underlying detailed physical mechanisms are not yet fully understood. Later experiments have revealed completely new and unexpected properties and the study of two-dimensional systems is now one of the most challenging areas of research in physics.

Horst Störmer (German, 1949–, Fig. 6.131) discovered the fractional quantum Hall effect, for which he won the Nobel Prize in Physics in 1998. The Royal Swedish Academy of Sciences summarized his work [https://www.nobelprize.org/prizes/physics/1998/stormer/facts/] :

> The Hall effect refers to the fact that if an electrical current flows lengthwise through a metal band and a magnetic field is placed against the surface of the band at a right angle, a charge arises diagonally in the band. In interfaces in certain materials a quantum Hall effect occurs. Klaus von Klitzing discovered that changes in the magnetic field result in changes in what is known as Hall conductance that vary in steps of whole-number multiples of a constant. Subsequently, Horst Störmer and Daniel Tsui discovered in 1982 that there also are steps that represent fractions of the constant.

Klaus von Klitzing (1943–)
1985 Nobel Prize in Physics
Quantum Hall effect

Horst Störmer (1949–)
1998 Nobel Prize in Physics
Fractional quantum Hall effect

In the quantum Hall effect, the electrical conductivity of a semiconductor surface increases in "stair steps" as the strength of an applied magnetic field (B) is changed.

The fractional quantum Hall effect is similar but with smaller stair steps.

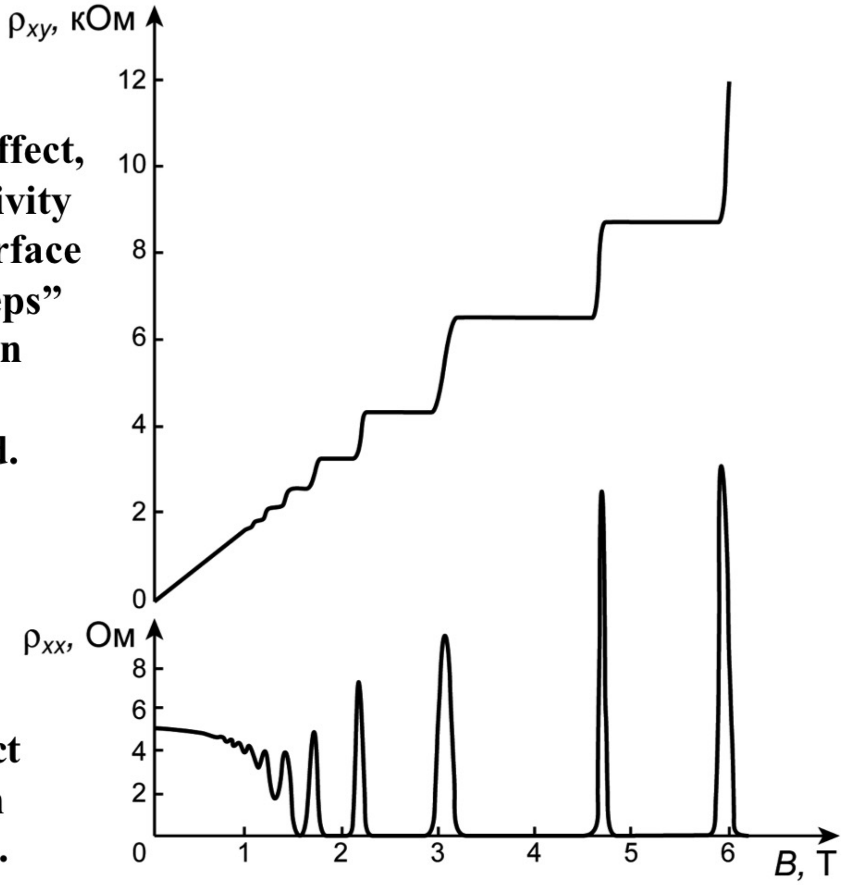

Figure 6.131: Klaus von Klitzing won the 1985 Nobel Prize in Physics for discovering the quantum Hall effect, and Horst Störmer won the 1998 Nobel Prize in Physics for the fractional quantum Hall effect.

6.5.10 Piezoelectricity

Piezoelectricity is an effect in quartz and certain other crystals in which small deformations of the crystal lattice (due to exerted pressure) shift the relative positions of charged ions and produce large electric fields and voltages. Thus piezoelectric crystals make ideal sensors for pressure or acceleration, convenient microphones to convert acoustic vibrations to electrical oscillations, and compact generators for producing high voltages for other components. The effect also operates in reverse—an applied voltage produces a small deformation of the crystal. Therefore, electrically stimulated piezoelectric crystals can be used as actuators to make small, controlled motions, for example by fine-tuning the focus of optical systems, oscillating to generate sound waves, or maintaining a constant vibration frequency to serve as a time standard in a clock or watch.

Piezoelectricity was initially discovered by the French brothers Pierre Curie (1859–1906) and Jacques Curie (1856–1941) in 1880. Their discovery prompted further studies of piezoelectricity over the following decades in France, the United Kingdom, the United States, and elsewhere.

Yet it was especially in the greater German-speaking world that piezoelectricity received an enormous amount of research attention, with large numbers of scientists exploring natural and synthetic piezoelectric materials, devising theoretical explanations of piezoelectricity, and developing a wide range of applications for piezoelectric elements.[15] Some of the more prominent scientists are discussed below, and a few of them are shown in Figs. 6.132–6.134.

Woldemar Voigt (German, 1850–1919) was one of the first major scientists to study piezoelectricity in detail after its initial discovery. He spent many years conducting experiments on the topic, and he also developed the first good theoretical explanation for piezoelectricity. He published most of his insights in his 1910 textbook, *Lehrbuch der Kristallphysik.* Voigt used sophisticated tensor analysis to calculate piezoelectric effects, and he described 20 different classes of natural crystals that exhibited piezoelectric effects.

Independently of Voigt but in parallel with him, Wilhelm Röntgen (German, 1845–1923) also spent many years investigating piezoelectricity. He finally published most of his results in 1914. Directly through their teaching and mentorship, and indirectly through their publications, Voigt and Röntgen inspired large numbers of younger scientists throughout the predominantly German-speaking scientific world to study and harness piezoelectricity.

Scientists at Jena University and the Zeiss optical company in Jena collaborated to study piezoelectric vibrations and the optical effects they could produce. Those scientists included (in alphabetical order): H.E.R. Becker (German, 18??–19??), Eduard Gerber (German, 1907–1986), Ernst Grossmann (German, 18??–19??), Norbert Günther (German, 18??–19??), ?? Hehlgans (German, 18??–19??), Harald Straubel (German, 1905–1991), and Max Wien (German, 1866–1938). (After the war, Gerber led research on piezoelectric devices at the U.S. Army's Fort Monmouth lab [Fort Monmouth Historical Office 2008; Gerber-Stroh 2012].)

At Göttingen University, Elisabeth Bormann (German, 18??–19??), Max Born (German, 1882–1970, p. 1040), ?? Gockel (German, 18??–19??), Gustav Heckmann (German, 1898–1996), and Max von Laue (German, 1879–1960) worked out detailed theoretical explanations of piezoelectricity.

---

[15] Katzir 2006, 2018; BIOS 255; BIOS 552; BIOS 609; BIOS 724; BIOS 865; BIOS 1316; BIOS 1504; BIOS 1579; BIOS 1679; CIOS XXV-13; FIAT 575; FIAT 641; FIAT 642; FIAT 1098; NavTecMisEu 361-45.

Scientists at Breslau University developed piezoelectric devices for ultrasonic systems, acoustic levitation of small objects, and other applications. That research group included Hans Ludwig Bergmann (German, 1898–1959), Karl Bücks (German, 18??–19??), Erwin Fues (German, 1893–1970), ?? Kraefft (German, 18??–19??), ?? Lonn (German, 18??–19??), Hanfried Ludloff (German, 1899–1987), Hans Müller (German, 18??–19??), and Clemens Schaefer (German, 1878–1968).

At the Physikalisch-Technische Reichsanstalt (PTR), Udo Adelsberger (German, 1904–1992), Erich Blechschmidt (German, 18??–19??), Erich Giebe (German, 18??–19??), and Adolf Scheibe (German, 1895–1958) invented piezoelectric resonators that could be used as a very accurate frequency standard. Adelsberger later developed precise quartz clocks that were used to control timed reentry maneuvers by the U.S. Apollo spacecraft returning from the moon.

Working at Telefunken in Berlin, Rudolf Bechmann (German, 1902–1974), Kurt Heegner (German, 1893–1965), and Alexander Meissner (Austrian, 1883–1958) also created sophisticated piezoelectric resonators and conducted theoretical analyses of piezoelectricity. Bechmann continued his work in the United States after the war.

At Cologne University, H. R. Asbach (German, 19??–19??), Egon Hiedemann (German, 1900–1969), and K. H. Hoesch (German, 19??–19??) developed novel methods and applications involving the interactions of acoustic and optical waves in piezoelectric crystals.

Frankfurt University scientists such as Hermann Auer (German, 19??–19??), H. Doerffler (German, 19??–19??), and Richard Wachsmuth (German, 1868–1941) also carried out important work on piezoelectricity.

At Graz University, Berta Nussbaumer (Austrian?, 19??–19??) and Angelika Székely (Austrian?, 18??–19??) conducted experiments on piezoelectricity and its applications. Regrettably, historians of science seem to have paid little attention to these important female physicists.

Walter P. Kistler (Swiss, 1918–2015) developed sophisticated piezoelectric sensors before, during, and after World War II.

At Philips Eindhoven, B. van Dijl (Dutch, 19??–19??) and Balthasar van der Pol (Dutch, 1889–1959) studied and harnessed piezoelectricity.

There was a large research team working on piezoelectricity at Charles University and related institutions in Prague, carrying out X-ray studies and using piezoelectric vibrations. That team included ?? Dolejšek (Czech/Austrian, 19??–19??), ?? Jahoda (Czech/Austrian, 19??–19??), František Khol (Czech/Austrian, 19??–19??), Franz Krista (Austrian?, 19??–19??), Václav Petržílka (Czech/Austrian, 1905–1976), August Žáček (Czech/Austrian, 1886–1961), and L. Zachoval (Czech/Austrian, 19??–19??).

After World War II, large amounts of piezoelectric-related information, materials, and scientists were transferred from the German-speaking world to Allied countries (Fig. 6.135). See for example:

> BIOS 255. *Gas Turbine and Reciprocating Engine Activities.* [Piezoelectric sensors in engines]

Some of these documents also prove that German-speaking scientists developed piezoelectric sensors for aircraft engines and automobile engines before and during World War II, and that that technology was transferred to Allied countries after the war (Figs. 6.136–6.137). Piezoelectric sensors are now widely used in engines to optimize the operating conditions and report any problems.

See also the closely related research on sonar (p. 1241), ultrasound imaging (p. 1250), and other applications (p. 3181).

Please see Appendix B for much more information on some of the German-speaking creators and their creations in the field of microelectronics, as well as documents showing how those technologies were transferred to other countries.

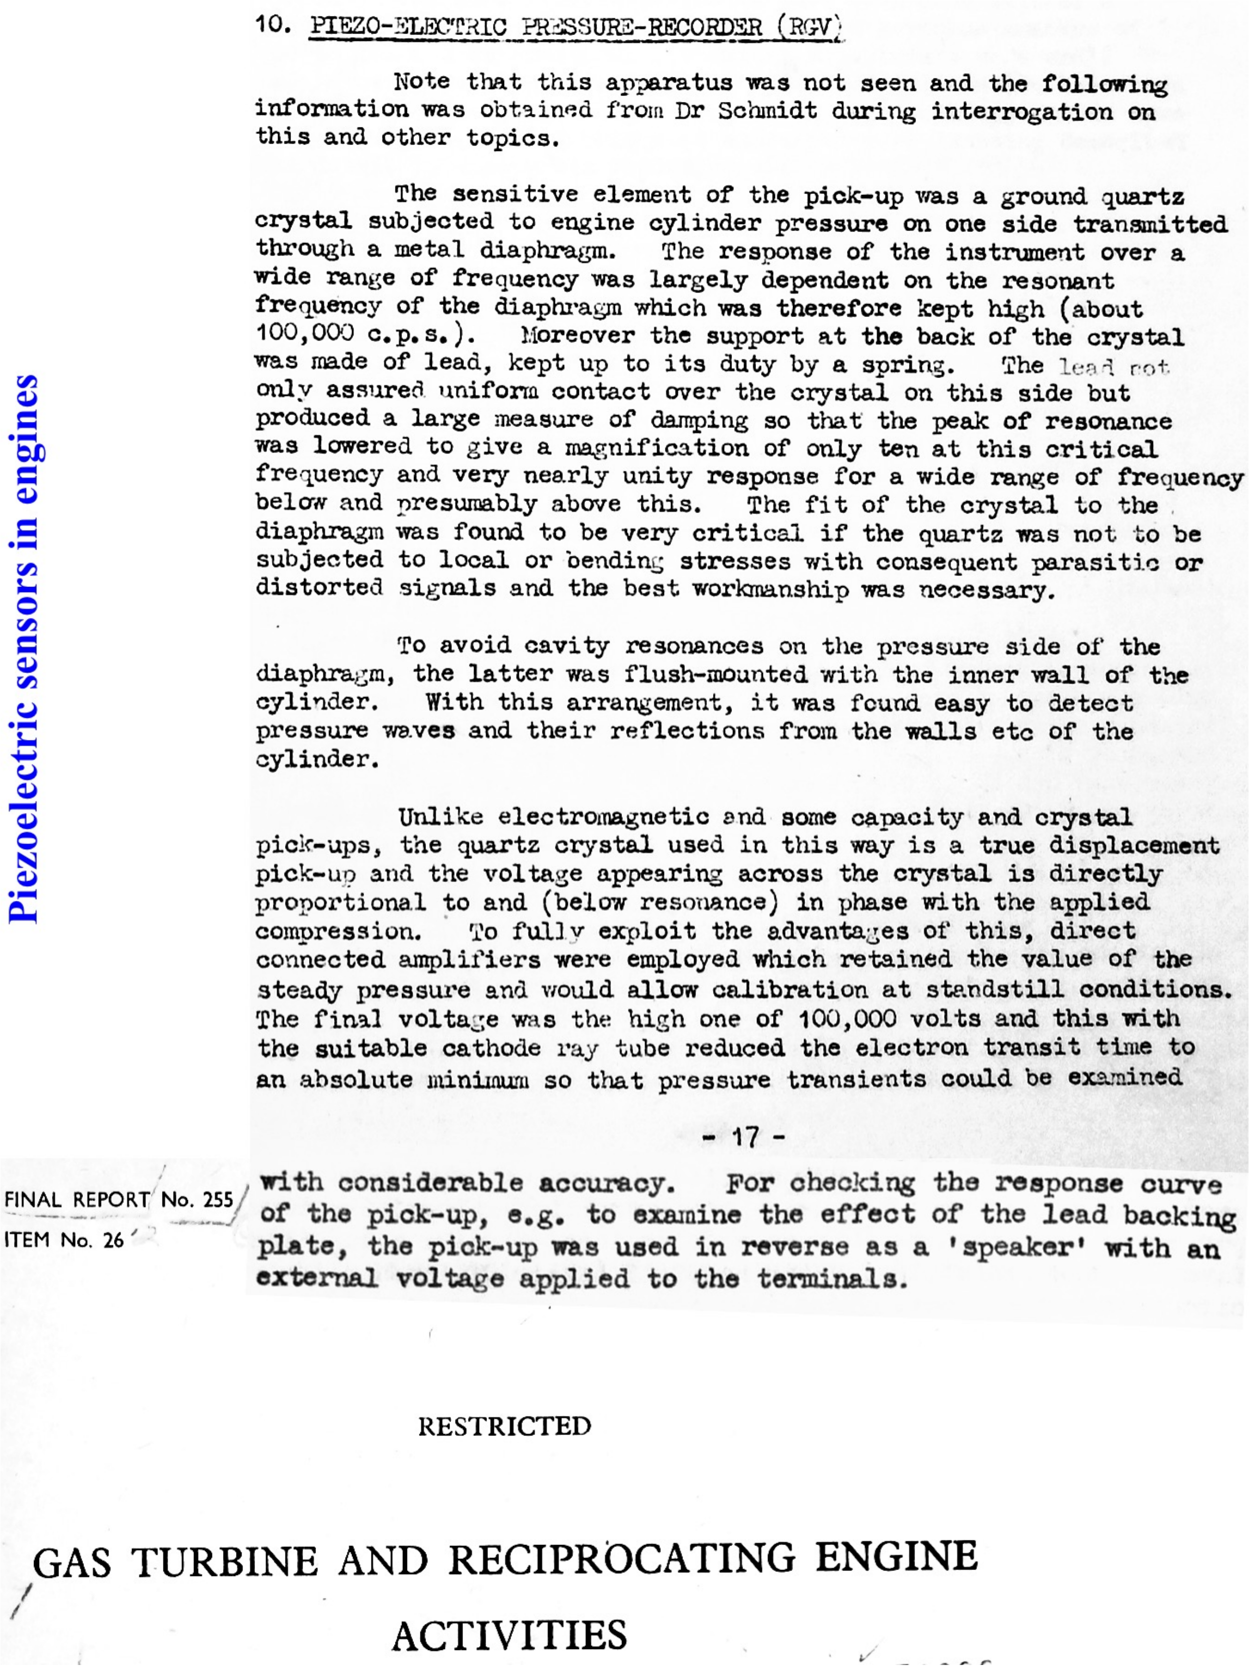
Piezoelectric sensors in engines



10. PIEZO-ELECTRIC PRESSURE-RECORDER (RGV)

Note that this apparatus was not seen and the following information was obtained from Dr Schmidt during interrogation on this and other topics.

The sensitive element of the pick-up was a ground quartz crystal subjected to engine cylinder pressure on one side transmitted through a metal diaphragm. The response of the instrument over a wide range of frequency was largely dependent on the resonant frequency of the diaphragm which was therefore kept high (about 100,000 c.p.s.). Moreover the support at the back of the crystal was made of lead, kept up to its duty by a spring. The lead not only assured uniform contact over the crystal on this side but produced a large measure of damping so that the peak of resonance was lowered to give a magnification of only ten at this critical frequency and very nearly unity response for a wide range of frequency below and presumably above this. The fit of the crystal to the diaphragm was found to be very critical if the quartz was not to be subjected to local or bending stresses with consequent parasitic or distorted signals and the best workmanship was necessary.

To avoid cavity resonances on the pressure side of the diaphragm, the latter was flush-mounted with the inner wall of the cylinder. With this arrangement, it was found easy to detect pressure waves and their reflections from the walls etc of the cylinder.

Unlike electromagnetic and some capacity and crystal pick-ups, the quartz crystal used in this way is a true displacement pick-up and the voltage appearing across the crystal is directly proportional to and (below resonance) in phase with the applied compression. To fully exploit the advantages of this, direct connected amplifiers were employed which retained the value of the steady pressure and would allow calibration at standstill conditions. The final voltage was the high one of 100,000 volts and this with the suitable cathode ray tube reduced the electron transit time to an absolute minimum so that pressure transients could be examined

- 17 -

with considerable accuracy. For checking the response curve of the pick-up, e.g. to examine the effect of the lead backing plate, the pick-up was used in reverse as a 'speaker' with an external voltage applied to the terminals.

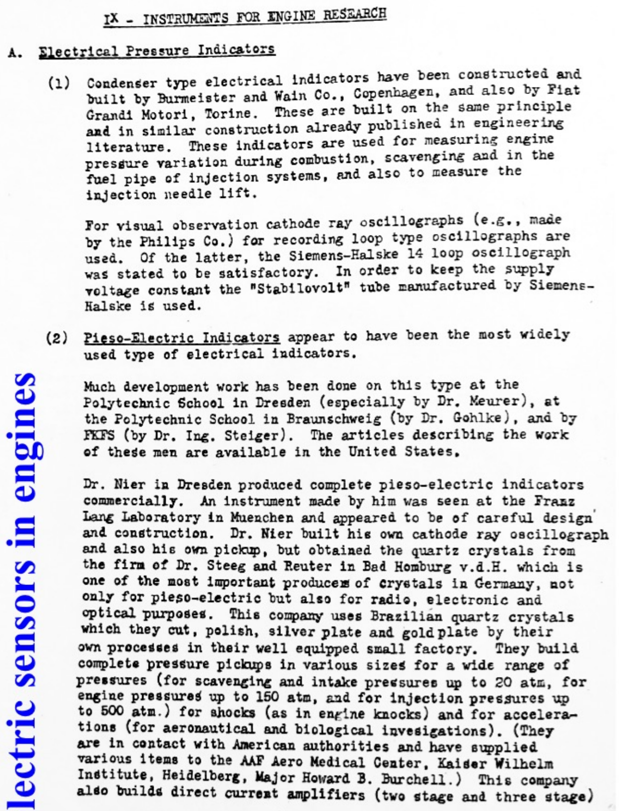
Piezoelectric sensors in engines



IX - INSTRUMENTS FOR ENGINE RESEARCH

A. Electrical Pressure Indicators

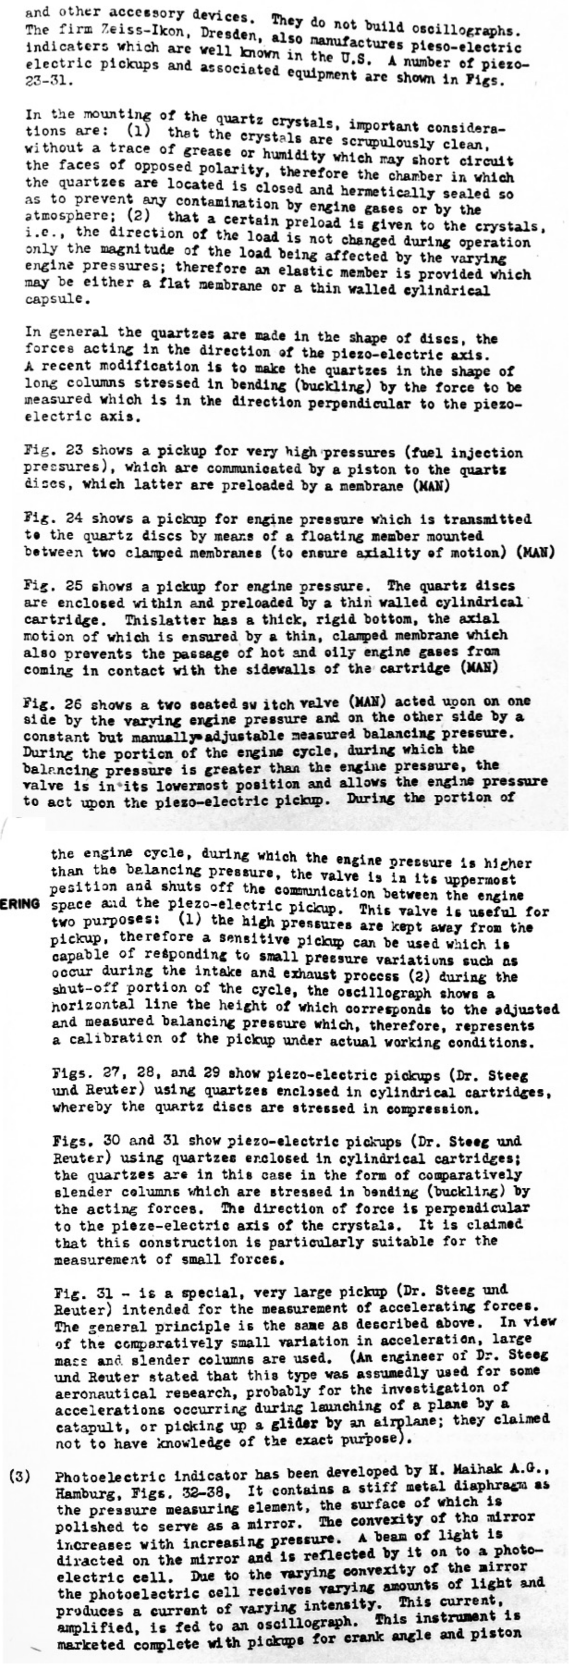
(1) Condenser type electrical indicators have been constructed and built by Burmeister and Wain Co., Copenhagen, and also by Fiat Grandi Motori, Torine. These are built on the same principle and in similar construction already published in engineering literature. These indicators are used for measuring engine pressure variation during combustion, scavenging and in the fuel pipe of injection systems, and also to measure the injection needle lift.

For visual observation cathode ray oscillographs (e.g., made by the Philips Co.) for recording loop type oscillographs are used. Of the latter, the Siemens-Halske 14 loop oscillograph was stated to be satisfactory. In order to keep the supply voltage constant the "Stabilovolt" tube manufactured by Siemens-Halske is used.

(2) Pieso-Electric Indicators appear to have been the most widely used type of electrical indicators.

Much development work has been done on this type at the Polytechnic School in Dresden (especially by Dr. Meurer), at the Polytechnic School in Braunschweig (by Dr. Gohlke), and by FKFS (by Dr. Ing. Steiger). The articles describing the work of these men are available in the United States.

Dr. Nier in Dresden produced complete pieso-electric indicators commercially. An instrument made by him was seen at the Franz Lang Laboratory in Muenchen and appeared to be of careful design and construction. Dr. Nier built his own cathode ray oscillograph and also his own pickup, but obtained the quartz crystals from the firm of Dr. Steeg and Reuter in Bad Homburg v.d.H. which is one of the most important producers of crystals in Germany, not only for pieso-electric but also for radio, electronic and optical purposes. This company uses Brazilian quartz crystals which they cut, polish, silver plate and gold plate by their own processes in their well equipped small factory. They build complete pressure pickups in various sizes for a wide range of pressures (for scavenging and intake pressures up to 20 atm, for engine pressures up to 150 atm, and for injection pressures up to 500 atm.) for shocks (as in engine knocks) and for accelerations (for aeronautical and biological invesigations). (They are in contact with American authorities and have supplied various items to the AAF Aero Medical Center, Kaiser Wilhelm Institute, Heidelberg, Major Howard B. Burchell.) This company also builds direct current amplifiers (two stage and three stage) and other accessory devices. They do not build oscillographs. The firm Zeiss-Ikon, Dresden, also manufactures pieso-electric indicaters which are well known in the U.S. A number of piezo-electric pickups and associated equipment are shown in Figs. 23-31.



In the mounting of the quartz crystals, important considerations are: (1) that the crystals are scrupulously clean, without a trace of grease or humidity which may short circuit the faces of opposed polarity, therefore the chamber in which the quartzes are located is closed and hermetically sealed so as to prevent any contamination by engine gases or by the atmosphere; (2) that a certain preload is given to the crystals, i.e., the direction of the load is not changed during operation only the magnitude of the load being affected by the varying engine pressures; therefore an elastic member is provided which may be either a flat membrane or a thin walled cylindrical capsule.

In general the quartzes are made in the shape of discs, the forces acting in the direction of the piezo-electric axis. A recent modification is to make the quartzes in the shape of long columns stressed in bending (buckling) by the force to be measured which is in the direction perpendicular to the piezo-electric axis.

Fig. 23 shows a pickup for very high pressures (fuel injection pressures), which are communicated by a piston to the quartz discs, which latter are preloaded by a membrane (MAN)

Fig. 24 shows a pickup for engine pressure which is transmitted to the quartz discs by means of a floating member mounted between two clamped membranes (to ensure axiality of motion) (MAN)

Fig. 25 shows a pickup for engine pressure. The quartz discs are enclosed within and preloaded by a thin walled cylindrical cartridge. Thislatter has a thick, rigid bottom, the axial motion of which is ensured by a thin, clamped membrane which also prevents the passage of hot and oily engine gases from coming in contact with the sidewalls of the cartridge (MAN)

Fig. 26 shows a two seated switch valve (MAN) acted upon on one side by the varying engine pressure and on the other side by a constant but manually-adjustable measured balancing pressure. During the portion of the engine cycle, during which the balancing pressure is greater than the engine pressure, the valve is in its lowermost position and allows the engine pressure to act upon the piezo-electric pickup. During the portion of the engine cycle, during which the engine pressure is higher than the balancing pressure, the valve is in its uppermost position and shuts off the communication between the engine space and the piezo-electric pickup. This valve is useful for two purposes: (1) the high pressures are kept away from the pickup, therefore a sensitive pickup can be used which is capable of responding to small pressure variations such as occur during the intake and exhaust process (2) during the shut-off portion of the cycle, the oscillograph shows a horizontal line the height of which corresponds to the adjusted and measured balancing pressure which, therefore, represents a calibration of the pickup under actual working conditions.

Figs. 27, 28, and 29 show piezo-electric pickups (Dr. Steeg und Reuter) using quartzes enclosed in cylindrical cartridges, whereby the quartz discs are stressed in compression.

Figs. 30 and 31 show piezo-electric pickups (Dr. Steeg und Reuter) using quartzes enclosed in cylindrical cartridges; the quartzes are in this case in the form of comparatively slender columns which are stressed in bending (buckling) by the acting forces. The direction of force is perpendicular to the pieze-electric axis of the crystals. It is claimed that this construction is particularly suitable for the measurement of small forces.

Fig. 31 - is a special, very large pickup (Dr. Steeg und Reuter) intended for the measurement of accelerating forces. The general principle is the same as described above. In view of the comparatively small variation in acceleration, large mass and slender columns are used. (An engineer of Dr. Steeg und Reuter stated that this type was assumedly used for some aeronautical research, probably for the investigation of accelerations occurring during launching of a plane by a catapult, or picking up a glider by an airplane; they claimed not to have knowledge of the exact purpose).

(3) Photoelectric indicator has been developed by H. Maihak A.G., Hamburg, Figs. 32-38. It contains a stiff metal diaphragm as the pressure measuring element, the surface of which is polished to serve as a mirror. The convexity of the mirror increases with increasing pressure. A beam of light is directed on the mirror and is reflected by it on to a photoelectric cell. Due to the varying convexity of the mirror the photoelectric cell receives varying amounts of light and produces a current of varying intensity. This current, amplified, is fed to an oscillograph. This instrument is marketed complete with pickups for crank angle and piston

6.6 Infrared Vision and Targeting

German-speaking creators played crucial roles in the development of infrared technologies, from the initial discovery of infrared light to the invention of infrared systems for night vision, optical communications, and heat-seeking missiles.[16] Those technologies were developed in Germany and Austria (Section 6.6.1) and then transferred to other countries after World War II (Section 6.6.2).

6.6.1 Development of Infrared Technologies

Using spectroscopy to search for energy beyond the colors of visible light, Friedrich Wilhelm (William) Herschel (Hanover, 1738–1822) discovered infrared light in 1800 [Herschel 1800]. See Fig. 6.138. He also discovered the planet Uranus and made several other important astronomical discoveries (p. 802).

Technologies such as photoelectric cells (p. 1046) and cathode ray tubes (p. 996) that had been invented by German-speaking scientists in the late nineteenth century and improved in the early twentieth century were later harnessed to detect infrared light for a wide variety of applications.

In 1941, Herbert C. J. Gaertner (German, 1906–19??) at the Zeiss optical company developed the Fahrgerät FG 1250 infrared vision system for nighttime driving. As shown in Fig. 6.139, the FG 1250 system combined a lamp that emitted only infrared light with a viewing scope that converted infrared to visible light. The FG 1250 system was also used for nighttime tank warfare (Fig. 6.140). Figure 6.141 shows an example of an armored vehicle with two FG 1250 infrared vision systems, one for a nighttime antiaircraft gun and another for nighttime driving.

The Uhu system was a closely related infrared vision system that was equipped with a larger nighttime infrared searchlight; see Fig. 6.142.

The Zielgerät 1229 Vampir (Vampire) infrared night-vision system for snipers was first operational in 1944. Figure 6.143 present photos of a ZG 1229 being demonstrated by a British soldier after the war. ZG 1229 and more advanced versions directly descended from it were rapidly adopted by Allied troops, and have been widely used ever since by everyone from soldiers to police to hunters.

Whereas the above systems all used relatively large viewing scopes, infrared viewing was also adapted to a compact binocular format, essentially producing the first infrared night-vision goggles. After the war, Allied investigators found prototypes of the infrared binoculars (Fig. 6.144) and used them as the basis for developing later versions of night-vision goggles.

Both infrared and visible light were employed for communications. In 1901, Ernst Ruhmer (German, 1878–1913) demonstrated a photophone that used visible light to transmit voice communications (Fig. 6.145). By World War II, the compact Zeiss infrared Lichtsprechgerät was used for efficient optical transmission of voice communications over distances up to several kilometers; see Fig. 6.146. The Lichtsprechgerät was also demonstrated with visible light. These systems were the direct forerunners of fiber optic communications that are now employed worldwide, except the light signals were transmitted through air instead of through transparent optical fibers. Optical glass fibers were also invented in the German-speaking world (p. 680). More archival research is needed to determine if optical fibers were ever used or considered for use in conjunction with optical data transmission in wartime Germany.

Another important application of infrared was in heat-seeking missiles that could automatically home in on the heat emitted by the engines of their target. As shown in Fig. 6.147, Edgar Kutzscher (German, 1906–1997) developed and demonstrated infrared tracking systems for heat-seeking missiles during the war. In fact, at least half a dozen different types of heat-seeking missile guidance systems were developed and built during the war. Figures 6.148–6.150 show some of their designs and creators.

After the war, Edgar Kutzscher discussed the development of the infrared photocells that were used in these heat-seeking missile guidance systems [Benecke and Quick 1957, pp. 208–209]:

> Practically all infrared devices developed before and during the war in Germany, and especially the devices which were used for detection of or homing on aircraft, used as receiver elements these photoconductive cells which we had developed at the ELEKTROACUSTIC CO. in Kiel. Dr. GOTTFRIED SOMMER, Dr. PICK, and Mr. KURT JUNG were my main co-operators in this part of the development.
>
> The cells which were available during the war fulfilled sufficiently the requirements of such an infrared detector. Extensive research and development work was still going on at the end of the war. [...] The lead sulphide cell of the ELEKTROACUSTIC CO. was produced by using a chemical precipitation method. Cells with various sizes and shapes of the sensitive area have been made. A large scale production was under way. Similar cells were developed by Dr. GÖRLICH at the laboratories of ZEISS-IKON in Dresden. GÖRLICH refined and used an evaporation method which was developed by the late Prof. GUDDEN.
>
> Much time and effort was spent in continuously improving the paramount properties of both types of cells, especially by modifying the production parameters and introducing the right impurities in the optimum amount.
>
> The sensitivity of those cells could be increased by a factor of 10 to 20 by cooling them. Liquid air and later solid CO_2 were used as coolants.

Kutzscher also described some of the heat-seeking systems and their creators [Benecke and Quick 1957, pp. 215–216]:

> Homing systems based on the principles described were developed by the ELEKTROACUSTIC CO. in Kiel, under the name “HAMBURG”. [...]
>
> For cases where the homing device detected the target before launching the missile, the homing device signals should be displayed to the pilot. For other cases, additional

infrared search devices installed in the aeroplane were developed. My main co-operators in the field of system development were Dr. RÜCKLIN, Dr. OCHMANN, Dr. AHRENS, Dr. HEITMÜLLER, and Dipl.-Ing. ORLICH.

Other infrared homing devices which were under development used in general the same principles we have discussed. The main difference between these various devices was the scanning method in order to obtain the angular information.

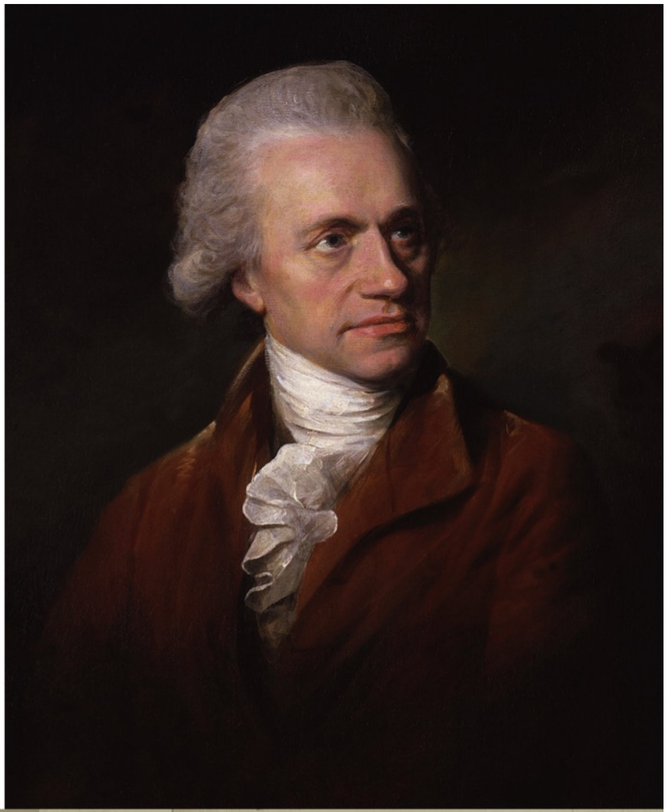
A device proposed by Dr. HILGERS of the AEG used a photocell with an area large enough to cover the total field of view in the focal plane. Two very narrow mechanical stops were moved perpendicular to each other across the cell. As soon as the image was covered by a stop a pulse was generated. [...] The firm KEPKA, in Vienna, used a similar principle by moving two narrow slits across the field. [...]

Mr. TRENKELFORD associated with RHEINMETALL-BORSIG developed a system for which the scanning was accomplished by two rotating discs, one of them having a spiral opening, the other one a slit. [...]

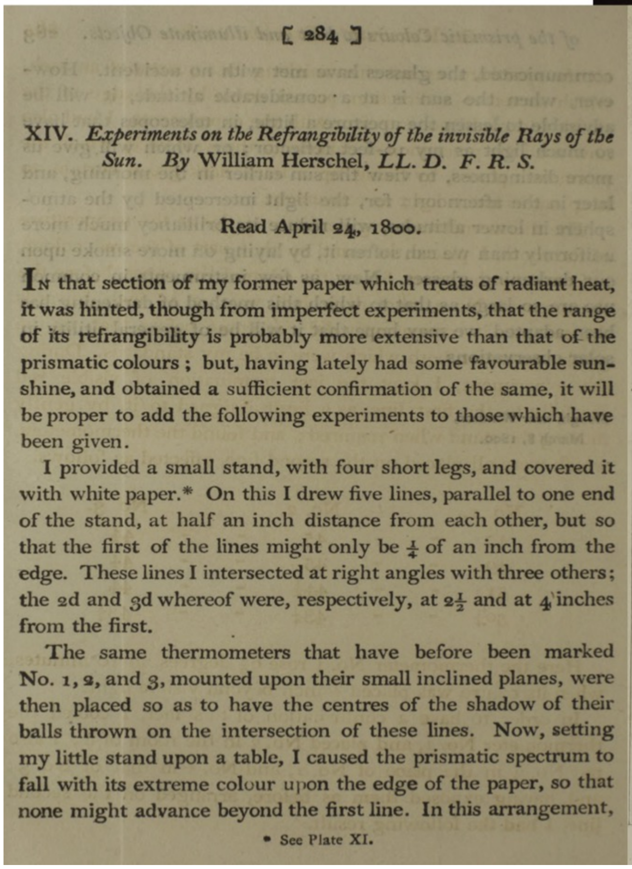
Dr. ORTHUBER of the AEG used a frequency modulation for scanning. The position of the target within the focal plane was given by a frequency, generated by two discs scanning the field of view. [...]

In conclusion, it should be noted that after considering the advantages and disadvantages of an infrared method and the results of the laboratory and field tests carried out on experimental devices, the people concerned were convinced in 1944 and 1945 that an infrared homing device constituted an excellent solution to certain guidance problems for missiles.

Friedrich Wilhelm (William) Herschel (1738–1822)



Discovered infrared light (1800)



[284]

XIV. *Experiments on the Refrangibility of the invisible Rays of the Sun. By* William Herschel, *LL. D. F. R. S.*

Read April 24, 1800.

In that section of my former paper which treats of radiant heat, it was hinted, though from imperfect experiments, that the range of its refrangibility is probably more extensive than that of the prismatic colours ; but, having lately had some favourable sunshine, and obtained a sufficient confirmation of the same, it will be proper to add the following experiments to those which have been given.

I provided a small stand, with four short legs, and covered it with white paper.* On this I drew five lines, parallel to one end of the stand, at half an inch distance from each other, but so that the first of the lines might only be $\frac{1}{4}$ of an inch from the edge. These lines I intersected at right angles with three others; the 2d and 3d whereof were, respectively, at $2\frac{1}{2}$ and at 4 inches from the first.

The same thermometers that have before been marked No. 1, 2, and 3, mounted upon their small inclined planes, were then placed so as to have the centres of the shadow of their balls thrown on the intersection of these lines. Now, setting my little stand upon a table, I caused the prismatic spectrum to fall with its extreme colour upon the edge of the paper, so that none might advance beyond the first line. In this arrangement,

After analyzing the German technologies, the U.S. Department of Commerce wrote an assessment (Fig. 6.151) praising how much more advanced they were than anything that the United States had possessed, and how much they would benefit the United States in the future [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards]:

> Information which has been secured concerning German developments accomplished in the field of infra-red light has proved to be of inestimable value to the military services of this country and will definitely effect an even greater contribution for our civilian purposes.
>
> Prior to the discovery of the German developments in this field, the United States had been unsuccessful in converting infra-red to visible light. Investigation has revealed that the Germans not only succeeded in converting infra-red light into visible light but also had been successful in its application for military purposes to a remarkable degree. They had applied this development in perfecting a spotlight which made possible the movement of army vehicles in total darkness without the use of visible illumination. By the use of another night-seeing device which the Germans used before the siege of Berlin, one of their tanks which was located in a woods, put sixty Russian tanks out of action by direct gunfire in total darkness as fast as the tanks came into view on a road which was a mile away from the German tank.
>
> The adaptation of similar device for use as a "sniperscope" enabled German snipers to fire effectively at Allied troops in total darkness at a range of 300 feet. Information obtained during interrogation of the first German prisoner who was captured with one of these units intact was immediately sent to this country where it was at first claimed that such a development was impossible. The device was then rushed to this country by air and production of it was started immediately. It was first used by American troops on Okinawa much to the bewilderment of the Japanese. Detailed information, including actual photographs of the captured German equipment is contained in Report No. PB-1587 made available by the Office of Technical Services of the Department of Commerce.

> The Germans also successfully applied infra-red light in the development of a device for voice transmission. This device permitted communication by means of an invisible light beam, without risk of interception, over short distances such as across rivers or valleys. A binocular attachment fitted with filters which made the infra-red beam visible, was used for focusing the wireless "telephone line". American industry is keenly interested in this device which has been evacuated to this country and is on loan to industry for test and research purposes. Information pertaining to this device is contained in Report No. PB-19746 published by the Office of Technical Services of the Department of Commerce.
>
> Some of the more obvious commercial applications of infra-red light developments thus revealed will be of inestimable value in the field of medicine, particularly in eye examination; and in the law enforcement field, where night-seeing can be employed in the detection of crime and the apprehension of criminals.

In addition to acquiring all of the infrared hardware, documentation, and information, the United States (and other countries) also hired many German-speaking experts to produce infrared systems after the war. Some examples include:

- Werner Karl Weihe (German, 19??–19??) developed infrared systems in Germany during the war, and at Wright Field, Ohio, after the war (Fig. 6.153).

- After the war, Hans K. Ziegler (German, 1911–1999) came to the United States in Operation Paperclip and became the Chief Scientist of a U.S. Army laboratory in Fort Monmouth, New Jersey, that employed many other German-speaking scientists and harnessed infrared and other technologies acquired from Germany and Austria [Fort Monmouth Historical Office 2008]. See Fig. 6.154–6.155.

- Edgar Kutzscher and other German-speaking creators used their wartime experience to develop postwar infrared heat-seeking missiles such as the U.S. Falcon and Sidewinder (Figs. 6.156–6.157).

- Heinz Schlicke (German, 1912–2006), an expert on infrared, electronics, and potentially nuclear-related technologies, arrived in the United States in May 1945 along with a whole German submarine filled with those technologies [AFHRA B1975, frames 1325–1495]. He spent the rest of his career in the United States. See pp. 4858–4892 for more information.

VIII

INFRA-RED

Information which has been secured concerning German developments accomplished in the field of infra-red light has proved to be of inestimable value to the military services of this country and will definitely effect an even greater contribution for our civilian purposes.

Prior to the discovery of the German developments in this field, the United States had been unsuccessful in converting infra-red to visible light. Investigation has revealed that the Germans not only succeeded in converting infra-red light into visible light but also had been successful in its application for military purposes to a remarkable degree. They had applied this development in perfecting a spotlight which made possible the movement of army vehicles in total darkness without the use of visible illumination. By the use of another night-seeing device which the Germans used before the siege of Berlin, one of their tanks which was located in a woods, put sixty Russian tanks out of action by direct gunfire in total darkness as fast as the tanks came into view on a road which was a mile away from the German tank.

The adaptation of similar device for use as a "sniperscope" enabled German snipers to fire effectively at Allied troops in total darkness at a range of 300 feet. Information obtained during interrogation of the first German prisoner who was captured with one of these units intact was immediately sent to this country where it was at first claimed that such a development was impossible. The device was then rushed to this country by air and production of it was started immediately. It was first used by American troops on Okinawa much to the bewilderment of the Japanese. Detailed information, including actual photographs of the captured German equipment is contained in Report No. PB-1587 made available by the Office of Technical Services of the Department of Commerce.

The Germans also successfully applied infra-red light in the development of a device for voice transmission. This device permitted communication by means of an invisible light beam, without risk of interception, over short distances such as across rivers or valleys. A binocular attachment fitted with filters which made the infra-red beam visible, was used for focusing the wireless "telephone line". American industry is keenly interested in this device which has been evacuated to this country and is on loan to industry for test and research purposes. Information pertaining to this device is contained in Report No. PB-19746 published by the Office of Technical Services of the Department of Commerce.

Some of the more obvious commercial applications of infra-red light developments thus revealed will be of inestimable value in the field of medicine, particularly in eye examination; and in the law enforcement field, where night-seeing can be employed in the detection of crime and the apprehension of criminals.

Authority NND 968148

As you know two representatives of the Signal Corp, Mr. Kaprillian, Chief of the Optical Division, and his assistant Dr. Keck, spent Monday, Tuesday and Wednesday opening and examining the contents of the trunks and documents stored at 15 Canal Street. So far, they have examined and labeled approximately 800 trunks. They were extremely complimentary of the cooperation given them by Mr. Sherwin and the men he assigned to assist.

Mr. Kaprillian and Dr. Keck have now returned to Fort Monmouth but will continue their work here next week and the week following. Mr. Kaprillian states that he believes the material contained in these trunks is worth $100,000,000 and so far the one or two dozen trunks of optics material, which he has discovered, will save the Signal Corp $30,000 in research and development. One trunk which they opened containing microfilm reels is believed to be a copy of all documents in these trunks. Mr. Kaprillian will write a letter of thanks to the Office of Technical Services for the assistance and cooperation which he has been given.

I should like to have your acquiescence to permitting the Signal Corp to transport to Fort Monmouth, via Army Truck, the several trunks of optics material. The documents will then be examined in minute detail, copied and important ones translated, and a copy of all translations will be furnished The Office of Technical Services for publication and distribution. All documents will then be returned to 15 Canal Street at Signal Corp expense.

6.7 Computers and Robotics

While it is not widely known in the modern non-German-speaking world, German-speaking scientists and engineers made numerous incredibly prescient advances in:

6.7.1. Calculating machines

6.7.2. Computers

6.7.3. Cryptography

6.7.4. Robotics

6.7.1 Calculating Machines

As shown in Fig. 6.158, Wilhelm Schickard (Tübingen, 1592–1635) designed, built, and demonstrated the first calculating machines. Computer historian Herman Goldstine [Goldstine 1993, p. 6] explained how modern scholars rediscovered Schickard and his accomplishments:

> Our story really opens during the Thirty Years War with Wilhelm Schickard (1592–1635), who was a professor of astronomy, mathematics, and Hebrew in Tübingen. Some years ago (1957) Dr. Franz Hammer, then assistant curator of Kepler's papers, discovered some letters from Schickard to Kepler—both of whom were from Würtemberg—containing sketches and descriptions of a machine Schickard had designed and built in 1623 to do completely automatically the operations of addition and subtraction and, partially automatically, multiplication and division. The first letter was dated 20 September 1623, and a subsequent one 25 February 1624. In the first one, Schickard wrote of the machine that it "immediately computes the given numbers automatically, adds, subtracts, multiplies, and divides. Surely you will beam when you see how [it] accumulates left carries of tens and hundreds by itself or while subtracting takes something away from them. . . ."

Gottfried Leibniz (Saxony, 1646–1716) greatly extended Schickard's work (Fig. 6.159). He produced a machine that could add, subtract, multiply, and divide fully automatically. Leibniz also designed machines that could do algebra and calculus. He created binary mathematics, the base-2 system in which numbers are represented by strings of 0s and 1s, which forms the foundation for modern computers. Leibniz even developed mathematical logic functions (AND, OR, NOT, etc.) that are used by digital circuits and modern computers [Antognazza 2009]. Herman Goldstine [Goldstine 1993, pp. 7–9] praised all of Leibniz's contributions to computer science:

> [...] Gottfried Wilhelm Leibniz (1646–1716), another of the great universalists of his or indeed of all time, invented a device now known as the *Leibniz wheel* and still in use in some machines. The mechanism enabled him to build a machine which surpassed Pascal's in that it could do not only addition and subtraction fully automatically but also multiplication and division. [...]
>
> [...I]t was Leibniz who summed up the situation very well indeed when he wrote: "Also the astronomers surely will not have to continue to exercise the patience which is required for computation. It is this that deters them from computing or correcting tables, from the construction of Ephemerides, from working on hypotheses, and from discussions of observations with each other. For it is unworthy of excellent men to lose hours

> like slaves in the labor of calculation which could safely be relegated to anyone else if machines were used." [...]
>
> Leibniz's work did however stimulate a number of others to build improved machines, many of them ingenious variants of his. Today these machines are still with us and play a significant role for minor calculations. Indeed during World War II they were of greatest importance.
>
> It is also Leibniz, who in the grandeur of his genius realized, at least in principle, his Universal Mathematics. This was also to have greatest importance to our story—but much later. He wrote an essay in 1666 concerning Combinatorics, one of the great branches of mathematics, entitled *De Arte Combinatorica.* He described it as "a general method in which all truths of the reason could be reduced to a kind of calculation." [...] Thus Leibniz contributed very profoundly to computers. Not only by his machine but also by his studies of what is now known as symbolic logic. [...] In closing our few paragraphs on Leibniz, we feel it is worth emphasizing his four great accomplishments to the field of computing: his initiation of the field of formal logics; his construction of a digital machine; his understanding of the inhuman quality of calculation and the desirability as well as the capability of automating this task; and lastly, his very pregnant idea that the machine could be used for testing hypotheses.

Herman Hollerith (1860–1929) was born in the United States, but his parents were German immigrants, and his father, a professor, apparently played a major role in his education and training. Hollerith developed electromechanical punch card machines that were widely used (Fig. 6.160). The company he founded to produce them later became International Business Machines (IBM). Oxford University's *Biographical Dictionary of Scientists* described Hollerith's innovation process [Porter 1994, pp. 341–342]:

> He was probably the first to automate the large-scale processing of information, and as such was a pioneer of the electronic calculator, particularly its application to data handling in business and commerce.
>
> [...] Hollerith developed the idea of punching first a continuous roll of paper, and later individual cards the same size as a dollar bill, with holes to represent information. The quantities indicated by the holes were counted when the tape or cards passed through a device in which electrical contact was made through the holes. The passage of an electric current caused electromechanical counters to advance one place for each hole. The realization of these ideas in practical terms did not, however, come about in time for the processing of the 1880 [census] returns. [...]
>
> By 1889, he had developed not only his electrical machines for recording the information on punched cards, but also machines for punching the cards and for sorting them. [...]
>
> Hollerith soon realized that the age of large-scale data handling had begun, and in 1896 he formed the Tabulating Machine Company, to manufacture the machines and the cards they used. With the growth of business in this area, Hollerith's company was soon merged with two others into the Computing-Tabulating-Recording Company, which later became International Business Machines Corporation (IBM). [...]
>
> Hollerith stayed with IBM as a consultant engineer until his retirement in 1921.

Herman Hollerith (1860–1929)
Electromechanical punch card machines

Figure 6.160: Herman Hollerith developed electromechanical punch card machines.

6.7.2 Computers

Gustav Tauschek (Austrian, 1899–1945) was an amazingly early, advanced, and prolific creator of computer technologies, as shown in Figs. 6.161–6.163 [Helfert et al. 2007]:

- From 1922 until his death in 1945, Tauschek designed, built, and patented a series of increasingly sophisticated programmable calculating machines that rivaled the computers that Zuse developed several years later, and surpassed any other computing machines in the world at that time.
- He invented the electric typewriter in 1927.
- Tauschek invented the world's first optical character recognition system in 1928.
- He also invented the world's first magnetic drum memories for computer data storage in 1929.
- IBM bought at least 169 of Tauschek's patents and used them as the basis of many of the machines that it built and marketed in the following decades.
- Along the way, Tauschek also invented lawnmowers, snowmobiles, the autopen or signing machine, and other devices.

Even though Tauschek's computer innovations were decades ahead of their time and exerted an enormous influence through his patents on IBM, and through IBM's products on the rest of the world, he has been virtually erased from history. Historians of computing worldwide should rediscover Tauschek and his work, and give him his proper place in the history books.

Konrad Zuse (German, 1910-1995), shown in Fig. 6.164, was another extremely early and important computer pioneer. He began designing and building prototype programmable digital computers in 1935. For his early Z1 and Z2 computers, he was assisted by people such as Helmut Schreyer (German, 1912–1984), who later developed his own computers. For his Z4 computer onward, he was assisted by people such as Heinz Rutishauser (Swiss, 1918–1970), who pioneered software and programming languages. Examples from Zuse's patents are provided in Fig. 6.165.

The first programmable digital computers built by Konrad Zuse included the:

- Z1 computer, which was first operational in 1938, was destroyed by Allied bombing during the war, and was rebuilt later as a museum piece (Fig. 6.166).
- Z2 computer, which was first operational in 1939, was destroyed during the war, and was never rebuilt (Fig. 6.166).
- Z3 computer, which was first operational in 1941, was destroyed in 1944, and was rebuilt after the war (Fig. 6.167).
- Z4 computer, which was first operational in 1944 and survived the war intact (Fig. 6.167).

- S1 special-purpose computer for measuring and calculating wing flutter, which was first operational in 1942, was destroyed in 1944, and was never rebuilt (Fig. 6.168).

- S2 special-purpose computer for measuring and calculating wing flutter, which was first operational in 1943 and was captured by Russian forces at the end of the war (Fig. 6.168).

In his autobiography, Zuse summarized the capabilities of the Z3 computer [Zuse 1993, pp. 62–63]:

> Z3 [...] was completed in 1941 and was the first fully operational machine to contain state-of-the-art versions of all the important elements of a program-controlled computing machine for scientific purposes[...] It had—in today's terminology—the following characteristics:
>
> – electromagnetic relay technology (600 relays in the arithmetic unit, 1400 relays in the memory unit)
>
> – binary number system
>
> – floating point
>
> – word length: 22 bits [...]
>
> – storage capacity: 64 words
>
> – control via an 8-track punched tape (i.e., a command is made up of 8 bits)
>
> – input entered via a special keyboard, through which the position of the points can be set relative to 4 decimal figures
>
> – output via display of results on a lamp strip, including the placement of the point
>
> – speed: approximately 3 seconds for multiplication, division or taking the square root
>
> [...] Yet the Z3 was relatively reliable. Unfortunately, I was the only one who could service it. [...]
>
> Aside from a few trial programs—programs to compute determinants or quadratic equations, for example—it was the program to compute a complex matrix that was of chief importance. This was an essential step in the computation of critical flutter frequencies of aircraft.

For the Z4 computer, Zuse increased the number of relays to approximately 2500 total, and the word length to 32 bits.

Zuse also developed the first high-level computer programming language, Plankalkül, in 1942 (Fig. 6.169). That was 14 years before IBM introduced the Fortran programming language, and may well have inspired and influenced the development of Fortran (through detailed postwar investigations of Zuse's work by Allied countries in general, and by IBM in particular).

In general, Zuse's first computers were years ahead of comparable technology that was later developed in the United States and other countries, and that was likely strongly influenced by Zuse's designs.[17] After the war, Zuse developed and sold a long series of commercial computers in Europe.

As illustrated in Fig. 6.170, Helmut Hölzer (German, 1912–1996) developed the world's first analog electronic computers beginning in 1939, including large mainframe computers and small onboard flight computers for rockets (p. 2814). Most of his work was conducted at and for the Peenemünde rocket research center [Tomayko 1985; https://www.cdvandt.org/v2__computer.htm]. After the war he went to the United States; in 1960 he became Director of Computers at the NASA Marshall Space Flight Center in Huntsville, Alabama.

Figure 6.171 presents some other early computer pioneers. Alwin Walther (German, 1898–1967) created and operated computers at Darmstadt for the Peenemünde rocket program during the war, and continued to develop computers after the war. Heinz Billing (German, 1914–2017) produced computers with magnetic drum and magnetic core memory, and later built the first laser-interferometer gravitational-wave detector; examples from his patents are shown in Fig. 6.172. Nikolaus Joachim Lehmann (German, 1921–1998) created computers in East Germany. As illustrated in Fig. 6.173, Walter Sprick (German, 1909–1989) developed computers ∼1939–1974; based on Sprick's designs, Heinz Nixdorf (German, 1925–1986) developed computers 1951–1986.

As shown in Figs. 6.175–6.178, creators who had been trained in the German-speaking research world also helped to develop computers in the United States. John von Neumann (Hungarian, 1903–1957) was involved in developing the first programmable digital computers in the United States, such as EDVAC (first operational in 1951). His wife, Klára Dán von Neumann (Hungarian, 1911–1963), was one of the first programmers on early computers such as MANIAC I (1952). Jan Rajchman (Polish, educated in Switzerland, 1911–1989) developed iron core computer memories and other computer technologies in the United States. Joseph Weizenbaum (German, 1923–2008) created the ELIZA software in 1965, a major step in the development of artificial intelligence.

It was German-speaking scientists who took magnetic computer memory from its very beginnings (Tauschek) to its most advanced form. Peter Andreas Grünberg (German, 1939–2018) discovered giant magnetoresistance, which can be used for high-density magnetic hard drives. For that discovery, he won the Nobel Prize in Physics in 2007. The Royal Swedish Academy of Sciences summarized his work [https://www.nobelprize.org/prizes/physics/2007/grunberg/facts/]:

> When materials are reduced to just a few atomic layers—a few nanometers in thickness—their properties change. Independently of one another, Peter Grünberg and Albert Fert discovered the phenomenon Giant Magneto Resistance (GMR) in 1988. GMR involves small changes in magnetic fields creating major differences in electrical resistance. It has also had an impact on electronics, especially read heads, where information stored magnetically is converted to electric current. Thanks to GMR, hard drives have become much smaller.

German-speaking scientists also developed magnetic tape, which for decades was used to store computer data as well as audio and visual signals (pp. 990, 1011).

UNITED STATES PATENT OFFICE

2,026,329

READING MACHINE

Gustav Tauschek, Vienna, Austria

Application May 27, 1929, Serial No. 366,466
In Austria May 30, 1928

26 Claims. (Cl. 250—41.5)

This invention relates to improvements in machines which are provided with arrangements adapted to create ray-images, particularly light ray images, of character or indications so as to cause by a comparing mechanism certain actions to be instituted thereby effecting the reading of such characters or indications, and thus replace reading by a person.

In order to attain this object the arrangement according to the present invention is provided with cells, in which the electric conductivity is varied by radiation, and with comparison devices which on the arrival of certain rays influencing the cells direct or control the corresponding operations.

The invention can be utilized for controlling any desired machine, however it will be found very useful in connection with office-machines, which heretofore could be operated only by persons who were able to read. Further the machine may be used for testing and counting securities, bank-notes and so forth and for controlling automatons and the like.

One of the modes of carrying out the present invention is illustrated diagrammatically by way of example on the accompanying sheet of drawing in which:—

Fig. 1 shows a perspective view of one construction, and

Fig. 2 is a detail view.

The embodiment shown in Fig. 1 serves for controlling the counting mechanism of a calculating machine. The record or sheet 1, provided with characters or the numerals for calculation, is placed on a base or carrier 2 in such a manner, that the number to be read is disposed opposite the lens 3, the record being illuminated by a strong source of light 4. On the other side of the lens 3 a suitable distance away, is arranged a photo-electric cell 5, in front of which rotates a movable device such as a wheel 6 constituting a portion of a comparison device, provided with stencil-recesses corresponding to the numerals 0 to 9. The stencil-recesses are of such a size and are shaped according to the numerals and are distanced in such a manner from the lens 3 that for instance the image of the numeral 1 exactly coincides with the stencil-recess as soon as the latter is disposed at the corresponding place. A contact wheel 7, provided with nine contact-knives 8 and supplied with current by way of a brush 9, is connected with the wheel 6. A contact-spring 10 is arranged opposite the contact wheel in such a manner, that the knives 8 establish electric connection during the rotation of the said contact wheel. A wire of an operating circuit 11 leads from the contact spring 10 to a control-magnet 12 which on being charged with current attracts the armature 13 and by way of a link 14 forces a pawl 15 against the action of a spring 16 into a toothed feed-wheel 17 and feeds forward the latter for the extent of a tooth. A number-wheel or number representing or manifesting wheel 18 is connected with the feed-wheel 17 and accordingly is fed forward also the extent of one place. In the circuit of the photo-electric cell 5 are included a low frequency transformer 39 and a relay-magnet 19, which controls the current supply of the brush 9. During the rotation of the wheel 6, rays of light will periodically pass to the cell 5 by way of the successive stencil-recesses of the wheel 6. The cell 5 is subjected to full light if a blank place of the sheet 1 is disposed opposite the lens 3. However a numeral, for instance the numeral 1, does not completely fill the other stencil recesses as shown in Fig. 2 by way of example of the stencil-recess corresponding to the Figure 2. Therefore light of the white writing sheet still passes to the cell 5. However a minimum of illumination of the cell 5 will take place, as soon as the stencil-recess corresponding to the numeral to be read is disposed in front of the cell. The relay 19 in the control circuit 38 is adjusted to this illumination-minimum and allows the withdrawal of its armature 21 by means of the action of the spring 20. In this way the contact member 22 is released and thus the current-supply to the brush 9 is interrupted. Supposing the numeral 1 is to be read off, a contact-knife 8 would already have passed the contact-spring 10 at the time of the release of the relay-armature 21 and the figure-wheel 18 would have been fed forward for a unit by the generated current. The eight following contact-knives 8 would remain inoperative, because the current-supply to the brush 9 is interrupted. Supposing the numeral 3 is to be read off, three contact-knives would have become operative, the figure-wheel would have been fed forward for three units and so forth.

Two cams 23 and 24 return the parts 21 and 22 into the initial position after each revolution of the wheel 6.

The wheel 6 with the numerals or other characters thereon, constitutes a movable search member or character-bearing comparison device in the path of the rays of radiant energy. With said device move the wheel 7 and its contact knives or blades 8, said parts 7, 8 constituting

Aus mechanischen Schaltgliedern aufgebautes Speicherwerk

Zusatz zum Zusatzpatent 919 017
Patentiert im Gebiet der Bundesrepublik Deutschland vom 3. Juli 1937 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Das Hauptpatent 907 948 hat angefangen am 9. Mai 1936
Patentanmeldung bekanntgemacht am 18. Juni 1953
Patenterteilung bekanntgemacht am 13. Januar 1955

Im Patent 919 017 und dessen Hauptpatent 907 948 sind mechanische Schaltglieder beschrieben, deren Aufgabe es ist, zweifach variable Angaben ähnlich elektrischen Relais miteinander rechnerisch zu kombinieren. Beim mechanischen Schaltglied werden die Angaben durch Blechstellungen dargestellt, und die Übertragung bzw. Neubildung von Angaben erfolgt durch Blechausschnitte, die mit Stiften im Eingriff stehen. In den erwähnten Patentschriften sind in der Hauptsache drei Arten von Schaltgliedern beschrieben:

1. das Normalschaltglied, bei dem durch ein Steuerblech zwei senkrecht dazu bewegliche Bleche miteinander verbunden werden (Patent 907 948, Abb. 2),

2. das Verteilerschaltglied, bei dem Angaben von einem Blech auf ein anderes übertragen werden (Patent 919 017, Abb. 1, 2, 3, 5),

3. das Speicherschaltglied, das die Aufgabe hat, eine zweifach variable Angabe zu speichern (Patent 907 948, Abb. 3, 6, 7).

PATENTSCHRIFT NR. 172288

Ausgegeben am 25. August 1952

DIPL. ING. KONRAD ZUSE IN WIEDEMEN (BAYERN, DEUTSCHLAND)

Vorrichtung zum Ableiten von Resultatangaben mittels Grundoperationen des Aussagenkalküls

Angemeldet am 2. April 1947. — Beginn der Patentdauer: 15. Feber 1952.

Die Erfindung betrifft eine Vorrichtung zum Ableiten von Resultatangaben aus irgendwelchen gegebenen Angaben nach einer Vorschrift. Unter einer Aussage (Angabe) ist beispielsweise jeder Satz zu verstehen, von dem es sinnvoll ist, zu behaupten, daß sein Inhalt richtig oder falsch ist. Aus mehreren Aussagen können nun durch Verknüpfungen (Operationen des Aussagenkalküls) wieder neue Angaben (Resultatangaben) gebildet werden, die richtig oder falsch sein können. Solche Grundoperationen des Aussagenkalküls sind beispielsweise:

1. Konjunktion: $A \,\&\, B$ (A und B)
2. Disjunktion: $A \vee B$ (A oder B)
3. Negation: $\overline{A}$ (nicht A)

Durch mehrfache Anwendung der Grundoperationen lassen sich komplizierte Angabenverknüpfungen (logistische Formeln mit einer Vielzahl von Variablen) bilden, aus denen nach Einsetzen bestimmter Werte (Ja-Nein-Werte) an die Stelle der beteiligten Variablen nach den Vorschriften des Aussagenkalküls eine Resultatangabe abgeleitet werden kann, die ihrerseits wieder eine Angabe über die Richtigkeit der in Frage stehenden logistischen Formel, also wiederum einen Ja-Nein-Wert darstellt.

Ein Beispiel soll dies veranschaulichen: Auf den üblichen Karteikarten zur Erfassung der Angestellten eines Betriebes sei auch eine Spalte vorgesehen, auf der untereinander die Buchstaben a bis i vermerkt sind, neben denen eine freie Stelle mit einem + oder — bezeichnet bzw. gelocht oder nicht gelocht ist.

Die Buchstaben bedeuten bestimmte Angaben, wie:

a = männlich
b = Inländer
c = verheiratet
d = abgeschlossene Hochschulbildung
e = bezieht ein Einkommen über 500 DM
f = über 10 Jahre im Betrieb
g = technische Fachkraft
h = kaufmännische Fachkraft
i = vollkommen gesund

Die Karteikarte des Angestellten M. sei folgendermaßen gekennzeichnet:

$a = +$
$b = +$
$c = -$
$d = +$
$e = +$
$f = -$
$g = +$
$h = -$
$i = -$

Demnach ist der Angestellte M. ein nicht verheirateter Inländer mit abgeschlossener Hochschulbildung, bezieht ein Einkommen über 500 DM, ist nicht über 10 Jahre im Betrieb und ist technische Fachkraft, nicht kaufmännische Fachkraft und nicht vollkommen gesund.

Es mag nun die Anweisung vorliegen, alle Angestellten auszuwählen, die bestimmten Voraussetzungen genügen, wobei diese Voraussetzungen in Form einer logistischen Formel (Auswahlformel) vorgeschrieben werden können, die etwa lautet:

$$(a \,\&\, b \,\&\, h) \vee (\overline{a} \,\&\, c \,\&\, f \,\&\, i) \vee (a \,\&\, \overline{c} \,\&\, d \,\&\, \overline{f} \,\&\, \overline{h})$$

Es werden also folgende Angestellte gesucht:

Männer, die Inländer und Kaufleute sind,
oder verheiratete Frauen, die über 10 Jahre im Betrieb und vollkommen gesund sind,
oder unverheiratete Männer mit abgeschlossener Hochschulbildung, die nicht über 10 Jahre im Betrieb und nicht kaufmännische Fachkräfte sind.

Der Angestellte M. fällt, wie eine Überlegung ergibt, unter die letzte Gruppe, genügt also der Auswahlformel.

Es ist der Zweck vorliegender Erfindung, solche logistische Aufgaben maschinell zu lösen, was erfindungsgemäß in der Weise geschieht, daß z. B. entsprechend gelochte Karteikarten maschinell abgetastet und verschiedene, den Lochstellen jeweils zugeordnete Relais zur Aufnahme der Eingangswerte hiebei an Spannung gelegt werden oder nicht. Über eine Verknüpfungsschaltung wird in zeitlicher Folge nach den

Schließlich muß n[illegible] Kriterium für R_1 gebildet werden.
R_1 kann nur im Falle V > 0 positiv werden, und zwar wenn bei V in den Stellen n-1 bis n-1-V eine Ziffer auftritt, die von V verschieden ist.
(Es sind dies die Ziffern, die beim Aufwärtsschieben verloren gehen.)
Es gilt also:

```
V > 0 →[(Min(V  ,n)) [(V       ~V    ) ⇒ R]]
1            1        o        o          1
                      n-1-i    n-1
```

Dieser Ansatz kann mit dem Ansatz von S.36 zusammengefaßt werden.

Wir haben also folgenden Gesamtansatz:

```
P10.72  |  R(V      , V     ) ⇒ (R      , R)
A10.2.0 V|    o        1           o        1
        A|    10.2.0   10.2.0      10.2.0
        S|    1.n      1.m         1.n      o

      V|  W1(n) [0≤i + V<n →[V = R┐ i + V]]
      K|                1    o   o      1
                             i

      V|  V >0 →[(W1(Min(V, n)))[- ⇒ R | V       ~V    ⇒ R]]
      K|  1                 1          o | o       o        1
                                       i | n-1-i   n-1

      V|  V<0 →[(W1(Min(|V|+1, n)))[V     ⇒ R    ]]
      K|  1                 1         o       o
                                      n-1     n-1-i

V. Operationen mit positiven ganzen Dezimalzahlen.

1) Aufbau der Zahlen. A9.10 = n × S1.4 .

Die einzelnen Komponenten entsprechen den Dezimalziffern. Diese werden als 4-stellige [illegible] dargestellt:

0 0000
1 000L
2 00L0
3 00LL
4 0L00
5 0L0L
6 0LL0
7 0LLL
8 L000
9 L00L

Beispiele für Dezimalzahlen: n = 4 .

	Ziffer 3	Ziffer 2	Ziffer 1	Ziffer 0
305 =	0000	00LL	0000	0L0L
1792 =	000L	0LLL	L00L	00L0

2) Operationen mit Dez-Zahlen.

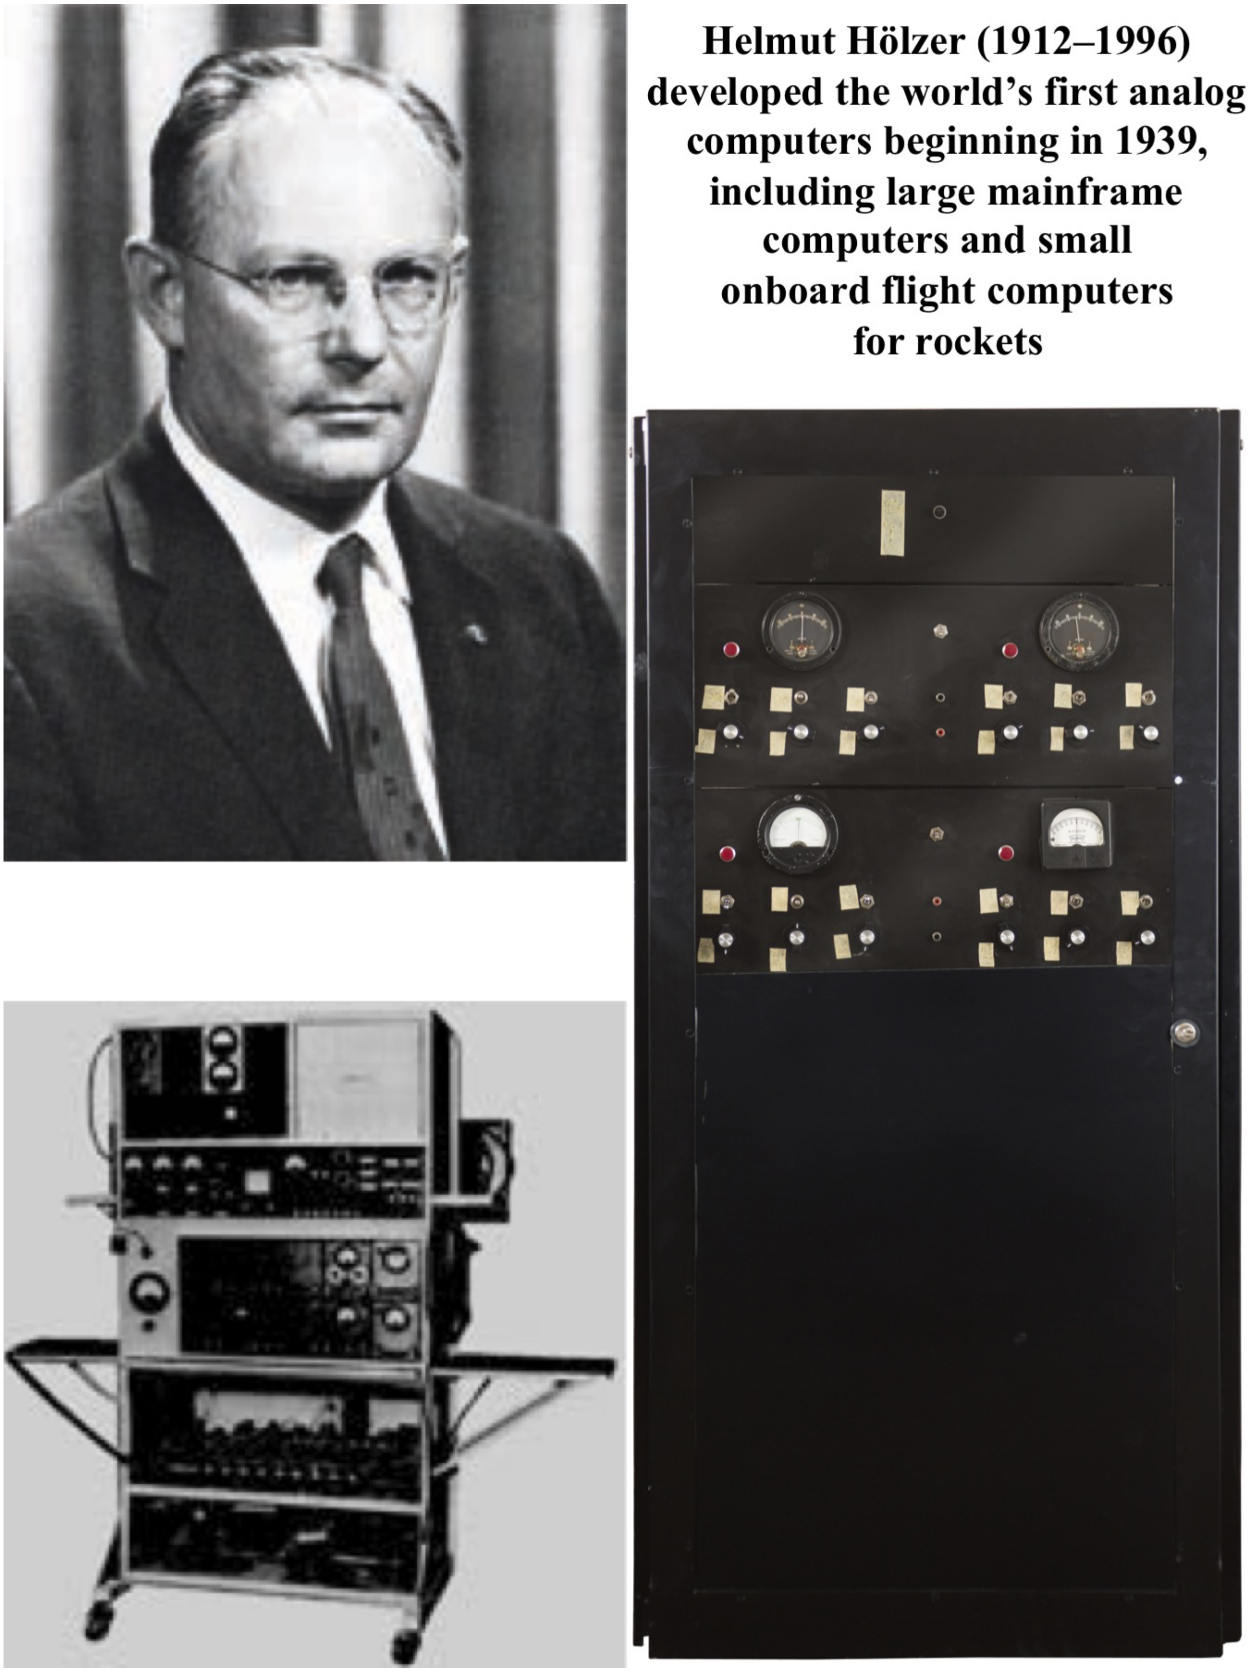
```
P9.64    V      + V      = R      | R = Meldung „Stellenbereich
A9.10    o        1        o      | 1             überschritten"
         9.10     9.10     9.10   |

    V| R(V      , V     ) ⇒ (R           , R)
    S|   o        1           o             1
         n×1.4    n×1.4       (n+1)×1.4     o
```

Die Bildung der Summe erfolgt ziffernweise. Es wird zuerst je Stelle aus den Werten V_0 und V_1 die Ziffernsumme $z_{0.i}$ gebildet.
Dieses ist eine 5-stellige Sek-Zahl. Findet eine Übertragung $z_{1.i}$ von der Stelle i-1 auf die Stelle i statt, so muß $z_{0.i}$ noch um Eins erhöht werden.

Ist der so gebildete Wert $z_{0.i}$ größer als 0L00L (9), so muß 10 subtrahiert werden, und dafür eine Übertragung $z_{1.i+1}$ auf die Stelle z_{i+1} stattfinden.

Figure 6.169: Konrad Zuse developed the first high-level computer programming language, Plankalkül (1942).



Helmut Hölzer (1912–1996) developed the world's first analog computers beginning in 1939, including large mainframe computers and small onboard flight computers for rockets

Aufrufvorrichtung für eine aus Magnetkernen bestehende Speichermatrix bei elektronischen Rechenmaschinen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 4. August 1953 an
Patentanmeldung bekanntgemacht am 8. September 1955
Patenterteilung bekanntgemacht am 13. Juni 1957

Obwohl bereits eine große Anzahl von Speicherverfahren für elektronische Rechenmaschinen bekannt ist, stellt bei solchen Maschinen der Zahlenspeicher immer noch das kritischste Element dar. Die wesentlichen Anforderungen an derartige Speicher sind Zuverlässigkeit, Einfachheit und möglichst niedrige Zugriffszeit. Diese drei Forderungen werden besonders gut durch magnetische Zahlenspeicher erfüllt, bei denen für die Speicherung jeder einzelnen Dualziffer jeder Zahl ein besonderer Magnetkern vorgesehen ist. Für die Magnetkerne solcher Speicher werden Kernmaterialien mit möglichst rechteckiger Hysteresisschleife verwendet und die einzelnen Magnetkerne in Form einer Matrix, also in Reihen und Spalten, angeordnet. Jeder Magnetkern erhält dabei mindestens zwei Wicklungen und die eine Wicklung jedes Kernes wird jeweils mit den entsprechenden Wicklungen der übrigen Kerne der gleichen Reihe und die andere Wicklung jedes Kernes mit den entsprechenden anderen Wicklungen der übrigen Kerne der gleichen Spalte in Serie geschaltet.

Bei einer solchen Magnetkernmatrix können beispielsweise die Magnetkerne der einzelnen Reihen für das Speichern von einer mehrstelligen Zahl benutzt werden. Die in Serie geschalteten Wick-

ARRANGEMENT FOR CONTROLLING IN CALCULATING MACHINES, OFFICE MACHINES AND THE LIKE
Heinz Billing and Wilhelm Hopmann, Gottingen, Germany, assignors to Max-Planck-Gesellschaft zur Förderung der Wissenschaften e.V., Gottingen, Germany
Filed Nov. 29, 1955, Ser. No. 549,816
Claims priority, application Germany Nov. 29, 1954
4 Claims. (Cl. 340—174)

This invention relates to electronic computing, calculating, and similar machines, and more particularly to an improvement of their control organisms.

Such a machine comprises, in addition to storage units and calculating or computing units proper, a command organism which controls the succession of the several operations. This command center includes a command register into which are fed the various commands as may be required for a desired result in the shape of command keys, and also includes control arrangements which, dependent upon the command fed to the command center, control the other parts of the machine. The various control arrangements constitute the control organism or center and the invention relates more particularly to an improvement of this control.

The purpose of the invention will now be explained referring by way of example to a machine of the parallel operation kind. However, similar arrangements could be used in conjunction with series machines.

The problem to be solved and the fundamental operating principles will now be described with reference to FIGS. 1, 2 and 3 of the accompanying drawings, FIGS. 4 to 11 showing various embodiments of the invention.

FIG. 1 shows diagrammatically the combination and association of the various parts of a calculating machine;

FIG. 2 shows the interconnection between a command register and a control center of the machine;

FIG. 3 shows such a control arrangement of conventional design;

FIG. 4 is the diagram of an electronic control arrangement according to the invention;

FIG. 5 comprises curves showing how the potentials at certain points of FIG. 4 vary with time;

FIG. 6 is a diagram of a control including a branched chain arrangement;

FIG. 7 shows a further development including several branches;

FIG. 8 shows a ring chain arrangement;

FIG. 9 shows another embodiment in which certain portions of the chain can be omitted by skipping;

FIG. 10 shows a matrix suitable for controlling the first elements of a control chain; and

FIG. 11 shows the connection diagram for a deciphering unit suitable for operating the control chains.

The arrangement of FIG. 1 includes a storage unit **1** and a calculating unit with three readily accessible registers, namely a multiplicand register **2** which is also indicated $\mathrm{M}d$, a multiplier register **5** also indicated $\mathrm{M}r$, and an accumulator **4** also indicated $\mathrm{A}k$. A command register **6** indicated $\mathrm{B}r$, and an adding device **3** indicated $\mathrm{A}d$ are also provided.

The register **2** connected to the storage unit **1** is supplied with the multiplicand, and the register **5** is supplied with the multiplier if a multiplication is to be carried out. Between the $\mathrm{M}d$ register **2** and the accumulator there is an adding device **3** so that the contents of $\mathrm{M}d$ can be added to the accumulator as required, and the results of the various calculating operations appear in the accumulator.

The command register **6** is supplied with the various calculation commands before the start of each calculating operation. Each command comprises an address

2

portion constituted by the number of the storage unit, the contents of which is used for the calculating operation, and an operating portion which determines the kind of the calculating operation required. For instance a command $\mathrm{LS}p$ means "read the storing unit" or in other words transfer the contents of the storage unit indicated in the command register to the $\mathrm{M}d$ register. All the registers are so interconnected that the contents of one register can be transferred to any of the other registers if a suitable command is given. For instance, the command "$\mathrm{M}d \rightarrow \mathrm{M}r$" means "shift the contents from $\mathrm{M}d$ to $\mathrm{M}r$." Furthermore, the digits of a number within each register can be shifted to the left or to the right by a respective command. Such command may be $\mathrm{M}d \rightarrow 1$ or $\mathrm{M}r \rightarrow r$, for instance. All the various calculating operations such as multiplication, division, square roots and so on, can be obtained by combining such sub-commands including addition, transfer, shifting, and other simple operations. The main command defines the actual calculation and is composed of a number of sub-commands.

For a better understanding two simple examples will now be described.

1st main command

Transfer a number from the storage unit designated in the command register to the accumulator and cancel multiplicand register.

This main command is composed of the sub-commands $\mathrm{LS}p$, $\mathrm{A}d$, $\mathrm{M}d \rightarrow 0$.

The sub-command $Md—0$ results in the cancellation of the $\mathrm{M}d$ register.

2nd main command

Multiply the number from the storage unit designated in the command register by the number in the accumulator.

For greater simplicity it is assumed that both numbers are given in the dual or binary system and that each comprises twenty digits. This main command requires a sub-command $\mathrm{A}d?$, meaning that the contents of $\mathrm{M}d$ should be added to the accumulator only if the lowest digit in the $\mathrm{M}r$ register is one. Then the main command "multiplication" is composed of the following sub-commands:

$$\mathrm{A}k \rightarrow \mathrm{M}r,\ \mathrm{LS}p,\ (\mathrm{A}d?,\ \mathrm{M}r \rightarrow r,\ \mathrm{M}d \rightarrow 1)$$

$$(\mathrm{A}d?,\ \mathrm{M}r \rightarrow r,\ \mathrm{M}d \rightarrow 1)\ \ldots\ \mathrm{M}r \rightarrow 0,\ \mathrm{M}d \rightarrow 0$$

The sub-commands in brackets are repeated twenty-times so as to form and add together the partial products as is known in binary multiplication.

These examples show the main problem of the control centre which is to ensure the correct sequence of sub-commands in accordance with a main command introduced into the command register. Generally a subsequent sub-command must not be started before a previous sub-command is completed.

The problem of the invention will be further explained with reference to FIG. 2, which shows a command register **6** interconnected with a deciphering pyramid **7** for selecting one of thirty-two possible main commands **H1** to **H32**.

The squares **U1** to **U20** indicate elements or units for initiating twenty sub-commands. An intermediary control **8** interconnects the deciphering pyramid **7** with the sub-command elements. After a sub-command is completed a "finish" signal is returned to the control **8** which can now initiate a subsequent sub-command. With some kinds of control arrangements the "finish" signal can be dispensed with if a sufficient time interval between initiations of consecutive sub-commands is allowed to insure that one sub-command is completed before another one

SECRET

Device For Transforming Spoken Words Into Recorded Legible Typewriting

One German wartime development which was discovered by one of the investigators for the Electronics and Communications Section is a device which has been the dream of American scientists in the communications field for a long time, one on which they have been working for many years, unsuccessfully.

Professor Oskar Vierling of the Feuerstein Laboratory at Ebermanstadt, Germany, developed the idea completely for the successful application of the fundamental principles to be employed in producing a device which will take the spoken word and transform it into the typewritten word on paper. The fundamental principles employed involve the separation of the sound waves produced by spoken words into nine bands of the sound range of the human ear and the actuation of a typewriting device by means of the transmission of the electrical vibrations resulting from the sound waves produced by the spoken words.

It is, therefore, readily discernible that the application of these principles will eliminate the need for stenographic transcription because it will provide the means for dictating a letter into a machine that will instantaneously reproduce in the form of a typewritten letter the words that are spoken into the machine. By the same token, a message dictated into a teletypewriter equipped with the device will appear simultaneously in typewritten form on every teletypewriter on a nationwide or worldwide network.

Transmission by means of this device can be accomplished with much greater speed than is otherwise possible. Consequently, the application of the device for transmission of messages by the communications companies will have further economic advantages because of the additional savings that can be accomplished in circuit use time. This is, of course, particularly true in the case of long-haul traffic handled on inter-city long distance communications channels.

Due to the possible application of this device for military communication purposes, the report containing detailed information pertaining to it is secret and is, therefore, not available to the public.

ELIZA—A Computer Program For the Study of Natural Language Communication Between Man And Machine

Joseph Weizenbaum
Massachusetts Institute of Technology, Cambridge, Mass.*

ELIZA is a program operating within the MAC time-sharing system at MIT which makes certain kinds of natural language conversation between man and computer possible. Input sentences are analyzed on the basis of decomposition rules which are triggered by key words appearing in the input text. Responses are generated by reassembly rules associated with selected decomposition rules. The fundamental technical problems with which ELIZA is concerned are: (1) the identification of key words, (2) the discovery of minimal context, (3) the choice of appropriate transformations, (4) generation of responses in the absence of key words, and (5) the provision of an editing capability for ELIZA "scripts". A discussion of some psychological issues relevant to the ELIZA approach as well as of future developments concludes the paper.

Introduction

It is said that to explain is to explain away. This maxim is nowhere so well fulfilled as in the area of computer programming, especially in what is called heuristic programming and artificial intelligence. For in those realms machines are made to behave in wondrous ways, often sufficient to dazzle even the most experienced observer. But once a particular program is unmasked, once its inner workings are explained in language sufficiently plain to induce understanding, its magic crumbles away; it stands revealed as a mere collection of procedures, each quite comprehensible. The observer says to himself "I could have written that". With that thought he moves the program in question from the shelf marked "intelligent", to that reserved for curios, fit to be discussed only with people less enlightened than he.

The object of this paper is to cause just such a re-evaluation of the program about to be "explained". Few programs ever needed it more.

ELIZA Program

ELIZA is a program which makes natural language conversation with a computer possible. Its present implementation is on the MAC time-sharing system at MIT. It is written in MAD-Slip [4] for the IBM 7094. Its name was chosen to emphasize that it may be incrementally improved by its users, since its language abilities may be continually improved by a "teacher". Like the Eliza of Pygmalion fame, it can be made to appear even more civilized, the relation of appearance to reality, however, remaining in the domain of the playwright.

For the present purpose it is sufficient to characterize the MAC system as one which permits an individual to operate a full scale computer from a remotely located typewriter. The individual operator has the illusion that he is the sole user of the computer complex, while in fact others may be "time-sharing" the system with him. What is important here is that the computer can read messages typed on the typewriter and respond by writing on the same instrument. The time between the computer's receipt of a message and the appearance of its response is a function of the program controlling the dialogue and of such MAC system parameters as the number of users currently corresponding with the system. These latter parameters generally contribute so little to the overall response time that conversational interaction with the computer need never involve truly intolerable delays.

When in conversation with ELIZA, the user types in some statement or set of statements in natural language using normal punctuation and sentence structures. Only the question mark may not be used, because it is interpreted as a line delete character by the MAC system. The user's statement is terminated by a double carriage return which serves to turn control over to ELIZA. ELIZA then analyzes the user's statement and generates some response which it types out. Control is then again with the user.

A typical conversation is the following:

```
Men are all alike.
IN WHAT WAY
They're always bugging us about something or other.
CAN YOU THINK OF A SPECIFIC EXAMPLE
Well, my boyfriend made me come here.
YOUR BOYFRIEND MADE YOU COME HERE
He says I'm depressed much of the time.
I AM SORRY TO HEAR YOU ARE DEPRESSED
```

Work reported herein was supported (in part) by Project MAC, an MIT research program sponsored by the Advanced Research Projects Agency, Department of Defense, under Office of Naval Research Contract Number Nonr-4102(01).

6.7.3 Cryptography

German-speaking experts revolutionized cryptography from World War I through the Cold War.[18]

Arthur Scherbius (German, 1878–1929) developed and filed patents on Enigma cryptography machines beginning in 1918, as shown in Fig. 6.180. Despite being relatively small and inexpensive, the Enigma machines were so effective at encryption and decryption that it required two decades, millions of British pounds, hundreds of special-purpose calculating machines, and stolen Enigma machines and Enigma codes in order to reliably decipher the encrypted messages. The Enigma machines were a WW-I-era German technology that was so far ahead of its time that the machines remained useful into World War II.

In contrast to popular stories in the English-speaking world about codebreaking at Bletchley Park in the United Kingdom, even the key insights involved in breaking the Enigma code came from other creators from the greater predominantly German-speaking scientific world, especially Marian Rejewski (Polish, 1905–1980), Jerzy Różycki (Polish, 1909–1942), and Henryk Zygalski (Polish, 1908–1978) [Hinsley 1979, Vol. 3, Part 2, pp. 945–959]. See Figs. 6.181–6.182. Rejewski, Różycki, and Zygalski began breaking simple Enigma codes in 1932. As more and more complex Enigma codes were used by the German military, Rejewski, Różycki, and Zygalski's codebreaking methods grew more advanced. By 1938, they had designed and built a "Bomba" decoding machine that used electromechanical gears to run through possible combinations and decipher Enigma messages. Soon they were forced to flee to France and then the United Kingdom. Built with their assistance, the British "Bombe" (1940) scaled up the Rejewski/Różycki/Zygalski system with many identical subunits in parallel. Popular accounts depicting the British as having conceived and implemented the Enigma decryption methods on their own [such as Hodges 1983 and its 2014 film adaptation, *The Imitation Game*] deny proper credit to the real creators.

Another fact omitted from most popular English-language histories is that rather than stopping with Enigma, German-speaking experts went on to develop far more advanced cryptographic machines and methods before and during World War II. Their advanced encryption and decryption machines, and the German-speaking experts themselves, later became the foundation for Cold War cryptography in other countries in the following decades.

Some of the advanced German encryption machines included:

- The Siemens and Halske T-52 Geheimschreiber (Fig. 6.183).
- The Siemens Schlüssel-Fernschreibmaschine SFM T-43 Sägefisch (Swordfish, Fig. 6.184).
- The Lorenz Schlüssel-Zusatz SZ42 (Fig. 6.185).
- Other encryption systems that were developed and used by wartime Germany and then seized by Allied countries after the war (e.g., Fig. 6.186).

Those machines were captured by Allied countries at the end of World War II and formed the basis of Cold War encryption for many years thereafter.

Along with the advanced encryption machines, German-speaking experts developed and used decryption computers to decipher coded transmissions from the United States, United Kingdom, Soviet Union, and other countries. Even highly secret coded messages between Washington and London were routinely intercepted and decrypted (Fig. 6.187). The German system for decrypting Soviet communications (sometimes called "Russian Fish") was especially advanced, and it accomplished a feat that the United States and United Kingdom had been unable to achieve (Fig. 6.188). That system was also captured by Allied countries and became the basis for much Cold War technology. Most of the details regarding the technology and its history remain secret even now.

In addition to the advanced encryption and decryption machines, Allied countries captured and utilized hundreds of highly skilled German and Austrian cryptographers. There were far too many of those cryptographers to list here, but some especially important ones who decrypted Allied coded communications during the war included Walter Fricke (German, 1915–1988), Erich Hüttenhain (German, 1905–1990), Kurt Vetterlein (German, 19??–19??), and Reinold Weber (German, 19??–19??), as shown in Fig. 6.188.

German-speaking creators such as Gustav Guanella (Swiss, 1909–1982) and Horst Feistel (German, 1915–1990) also made major contributions to cryptography after World War II. Fig. 6.190 presents examples from their patents on advanced cryptographic techniques.

Journalist James Bamford provided a rare glimpse into German cryptographic work that was discovered by the Allied TICOM (Target Intelligence Committee) team at the end of the war [Bamford 2002, pp. 8–18]:

> Colonel George A. Bicher, the director of the U.S. Signal Intelligence [Sigint] Division in Europe, conceived of TICOM in the summer of 1944. The organization was so secret that even today, more than half a century later, all details concerning its operations and activities remain classified higher than Top Secret by both the American and British governments. In 1992, the director of the National Security Agency extended the secrecy order until the year 2012, making TICOM probably the last great secret of the Second World War. [...]
>
> Although Bletchley Park had conquered the Enigma machine, the Germans had managed to go one better. They developed a new and even more secret cipher machine, the *Geheimschreiber*, or secret writer, which was reserved for the very-highest-level messages, including those to and from Hitler himself. German cryptographers called an early model Swordfish. The Americans and British simply called them the Fish. Unlike Enigma, the Fish were capable of automatically encrypting at one end and decrypting at the other. Also, rather than the standard 26-letter alphabet, the Fish used the 32-character Baudot code, which turned the machine into a high-speed teleprinter.
>
> TICOM's goal was to capture a working model intact and thus learn exactly how the Germans built such a complex, sophisticated encryption device. [...]
>
> With enough Fish and other equipment to keep the engineers busy for a long time at Bletchley, the team began a manhunt for key German codebreakers. On May 21, 1945, Lieutenant Commander Howard Campaigne and several other TICOM officers interviewed a small group of Siginit personnel being held in Rosenheim. They had all worked for a unit of the Signals Intelligence Agency of the German Abwehr High

Command, a major target of TICOM. What the prisoners told Campaigne would lead to one of the most important, and most secret, discoveries in the history of Cold War codebreaking. Their command, they said, had built a machine that broke the highest-level Russian cipher system. [...]

It was a massive haul of some 7½ tons.

Over the next several days the dark gray equipment was carefully lifted from its crates and set up in the basement of the building. Then, like magic, high-level encrypted Russian communications, pulled from the ether, began spewing forth in readable plaintext. [...]

The Russian system involved dividing the transmissions into nine separate parts and then transmitting them on nine different channels. The German machines were able to take the intercepted signals and stitch them back together again in the proper order. For Campaigne and the rest of the TICOM team, it was a once-in-a-lifetime discovery. Back in Washington, Campaigne would eventually go on to become chief of research at NSA. [...]

The discovery of the Russian codebreaking machine was a principal reason why both the U.S. and British governments still have an absolute ban on all details surrounding the TICOM operations.

All told, the TICOM teams salvaged approximately five tons of German Sigint documents. In addition, many cryptologic devices and machines were found and returned to Bletchley.

Equally important were the interrogations of the nearly 200 key German codebreakers, some of which were conducted at a secret location codenamed Dustbin. In addition to the discovery of the Russian Fish, another reason for the enormous secrecy surrounding TICOM may be the question of what happened to the hundreds of former Nazi codebreakers secretly brought to England. Were any of the war criminals given new identities and employed by the British or American governments to work on Russian codebreaking problems? Among those clandestinely brought into the United States was the top codebreaker Dr. Erich Huetterhain. “It is almost certain that no major cryptanalytic successes were achieved without his knowledge,” said one TICOM document.

SECRET

COMMUNICATIONS SECRECY SYSTEMS

Information which has been obtained pertaining to the communications secrecy systems developed by Professor Oskar Vierling in the Feuerstein Laboratory at Ebermanstadt, Germany, will prove to be of inestimable value for military purposes.

One of these systems which represents a modification of the usual plan for getting many sending frequencies from a single crystal resulted in the development of a compact multi-frequency crystal controlled radio set for the use of agents in enemy territory.

Another such development provided equipment whereby night fighter planes could be given instructions instantaneously by ground control intercept stations in much the same manner as the engine room of a ship receives operating instructions from the bridge. In night fighter operation, everything happens so quickly that it is of extreme importance to have the quickest possible ground-to-plane communications. This development provides an excellent answer to that problem.

In response to urgent wartime pressure resulting from the belief that coded telephone and teletypewriter messages were being decoded by the Allies, methods were developed by the Germans for increasing the effectiveness of the secrecy systems being used for that purpose. One of the systems the Germans developed for providing secrecy in telephone communications was very valuable due to the fact that anyone listening in to the scrambled speech thinks he hears perfectly good words, which are, however, quite wrong. The system that was developed for providing secrecy for teletype communications has also proved to be extremely effective.

Due to the possible military application of these developments, information pertaining to them is still classified as secret and is, therefore, not available to the public.

6.7.4 Robotics

The Jewish and greater German-speaking worlds had a centuries-long tradition of folklore regarding the creation of an artificial worker, or "Golem," out of inorganic materials (p. 2653). The concept of a Golem was especially prominent in the German-speaking world of the early twentieth century, featured in stories such as the 1913–1914 serialized novel *Der Golem* by Gustav Meyer/Meyrink (Austrian, 1868–1932) and in three films of the same name by Paul Wegener (German, 1874–1948) that were released in 1915, 1917, and 1920.

Apparently inspired by those stories, in 1920 Karel Čapek (Czech, 1890–1938) wrote the play *R.U.R. (Rossum's Universal Robots)*, in which he was the first to use the word "robot" to describe a factory-made artificial worker (Fig. 6.191) [Contrada 1995]. In Čapek's play, the manager of the factory producing the robots summarized the approach to creating them [Čapek 1923, Act I]:

> Young Rossum invented a worker with the minimum amount of requirements. He had to simplify him. He rejected everything that did not contribute directly to the progress of work. Everything that makes man more expensive. In fact he rejected man and made the Robot. My dear Miss Glory, the Robots are not people. Mechanically they are more perfect than we are; they have an enormously developed intelligence, but they have no soul. [...] Have you ever seen what a Robot looks like inside? [...] Very neat, very simple. Really a beautiful piece of work. Not much in it, but everything in flawless order. The product of an engineer is technically at a higher pitch of perfection than a product of Nature.

In the 1927 film *Metropolis*, Fritz Lang (Austrian, 1890–1976) and Thea von Harbou (German, 1888–1954) continued that theme by depicting the fictional creation of a robot (Maschinenmensch or machine-person) that was so lifelike that it could successfully impersonate a human woman (p. 1971).[19]

German-speaking scientists and engineers began making those general ideas a reality even before *R.U.R.* and *Metropolis* were released, and continued with even greater effort in the years afterward.[20]

In 1893, Nikola Tesla (Serbo-Croatian, educated in Austria, 1856–1943) began developing the world's first teleoperated robotic vehicles. By 1898, he patented and demonstrated a radio-controlled boat, and described how his approach could be extended to a wide variety of vehicles and much more elaborate control systems, and even to autonomously directed vehicles (Fig. 6.192). In his autobiography, Tesla summarized his work and his vision in the field of teleoperated vehicles and robotics [Tesla 1919, pp. 106–109]:

> The idea of constructing an automaton, to bear out my theory, presented itself to me early but I did not begin active work until 1893, when I started my wireless investigations. During the succeeding two or three years a number of automatic mechanisms, to be actuated from a distance, were constructed by me and exhibited to visitors in my laboratory. In 1896, however, I designed a complete machine capable of a multitude of operations, but the consummation of my labors was delayed until late in 1897. This machine was illustrated and described in my article in the Century Magazine of June, 1900,

---

[19] Bogdanovich 1967; Eisenschitz and Bertetto 1994; Eisner 1977; Jenkins 1981; McGilligan 1997.

[20] Cheney 1981; Cheney and Uth 1999; Everett 2015; Jaugitz 2001; Tesla 1919; Trenkle 1987.

and other periodicals of that time and, when first shown in the beginning of 1898, it created a sensation such as no other invention of mine has ever produced. In November, 1898, a basic patent on the novel art was granted to me, but only after the Examiner-in-Chief had come to New York and witnessed the performance, for what I claimed seemed unbelievable. I remember that when later I called on an official in Washington, with a view of offering the invention to the Government, he burst out in laughter upon my telling him what I had accomplished. Nobody thought then that there was the faintest prospect of perfecting such a device. It is unfortunate that in this patent, following the advice of my attorneys, I indicated the control as being effected thru the medium of a single circuit and a well-known form of detector, for the reason that I had not yet secured protection on my methods and apparatus for individualization. As a matter of fact, my boats were controlled thru the joint action of several circuits and interference of every kind was excluded. Most generally I employed receiving circuits in the form of loops, including condensers, because the discharges of my high-tension transmitter ionized the air in the hall so that even a very small aerial would draw electricity from the surrounding atmosphere for hours. Just to give an idea, I found, for instance, that a bulb 12" in diameter, highly exhausted, and with one single terminal to which a short wire was attached, would deliver well on to one thousand successive flashes before all charge of the air in the laboratory was neutralized. The loop form of receiver was not sensitive to such a disturbance and it is curious to note that it is becoming popular at this late date. In reality it collects much less energy than the aerials or a long grounded wire, but it so happens that it does away with a number of defects inherent to the present wireless devices. In demonstrating my invention before audiences, the visitors were requested to ask any questions, however involved, and the automaton would answer them by signs. This was considered magic at that time but was extremely simple, for it was myself who gave the replies by means of the device.

At the same period another larger telautomatic boat was constructed a photograph of which is shown in this number of the ELECTRICAL EXPERIMENTER. It was controlled by loops, having several turns placed in the hull, which was made entirely water-tight and capable of submergence. The apparatus was similar to that used in the first with the exception of certain special features I introduced as, for example, incandescent lamps which afforded a visible evidence of the proper functioning of the machine.

These automata, controlled within the range of vision of the operator, were, however, the first and rather crude steps in the evolution of the Art of Telautomatics as I had conceived it. The next logical improvement was its application to automatic mechanisms beyond the limits of vision and at great distance from the center of control, and I have ever since advocated their employment as instruments of warfare in preference to guns. The importance of this now seems to be recognized, if I am to judge from casual announcements thru the press of achievements which are said to be extraordinary but contain no merit of novelty, whatever. In an imperfect manner it is practicable, with the existing wireless plants, to launch an aeroplane, have it follow a certain approximate course, and perform some operation at a distance of many hundreds of miles. A machine of this kind can also be mechanically controlled in several ways and I have no doubt that it may prove of some usefulness in war. But there are, to my best knowledge, no instrumentalities in existence today with which such an object could be accomplished in

> a precise manner. I have devoted years of study to this matter and have evolved means, making such and greater wonders easily realizable.

As shown in Fig. 6.193, Anton Flettner (German, 1885-1961) filed patent applications on teleoperated robots beginning in 1906. He designed robots for various applications on land, in the water, and in the air. In 1915, he demonstrated a radio-controlled battlefield mini-tank with remote-controlled weapons (a blow torch in the demonstration model; the model is shown without its armored shell in Fig. 6.193). Flettner also invented rotor ships (p. 1484) and ultimately became most famous for creating helicopters (p. 1824). U.S. Navy robotics expert H. R. Everett presented information from several sources regarding the history of Flettner's work on teleoperated robots [Everett 2015, pp. 415–417]:

> In 1913, an up-and-coming German inventor named Anton Flettner [...] reportedly patented a radio-controlled "tank" in conjunction with the firm Felt-Guillaume-Lahnmeyer (Seydewitz and Doberer, 1937). Born into a family of ship owners on 1 November 1885 (Marine Review, 1926), Flettner grew up near Frankfurt on Main, where as a youth he became involved in the development and demonstration of radio control for riverboats (Hirschel et al., 2004, 299). As Flettner recounted in *Mein Weg zum Rotor*: "I was still a high school student in Hoechst on the Main when I made my first invention. I contrived to design a wireless distant control system whereby torpedoes, ships and other vehicles could be directed from a distance without any direct communication by wire or otherwise. My experiments were successful" (Flettner, 1926). [...]
>
> Following the outbreak of World War I, he was hired by the renowned Count Ferdinand von Zeppelin to investigate the feasibility of radio-controlled airships (Day and McNeil, 1996). [...]
>
> The gifted inventor's first brush with fame came the following year: "Flettner became known in his country and abroad in the summer of 1915, when a curious clumsy vehicle made its appearance in Berlin: a tank which could move in any direction without a crew. The whole program of the tank's maneuvers was being directed from an unknown spot in the distance" (Tokaty, 1994, 141). [...]
>
> In *Les rayons de la mort*, Seydewitz and Doberer (1937) indicate the tank was successfully controlled from a following car while crossing obstacles and breaching barbed wire. In addition to the basic mobility functions of *forward*, *reverse*, *left*, *right*, and *stop*, it also had an obstacle-clearing payload; Flettner (1926) described this feature in action: "In front of the wire entanglements constructed of angle iron the tank suddenly emitted the blinding hissing flames of an autogenous cutting device," and in a few minutes the obstacles were gone."

By the 1930s, Flettner had moved on to helicopters, but Werner Bergau (German, 1904–??), Robert Brüderlink (German, 1893–1978), Friedrich Gladenbeck (German, 1899–1987), and other German-speaking scientists and engineers took up Flettner's earlier work on robotic tanks (Fig. 6.194). They designed, built, optimized, and deployed rugged, teleoperated robotic systems to handle explosives and perform other complex tasks under actual battlefield conditions [Everett 2015; Jaugitz 2001; Trenkle 1987]:

- The small Leichter Ladungsträger Goliath was first deployed in 1942 (Fig. 6.194). It was primarily employed as a single-use vehicle to deliver demolition charges to bridges, enemy tanks, or other targets, although it was a versatile platform that could also be customized for other tasks. During the war, over 7500 Goliath units were produced and deployed to battlefields ranging from the Normandy beaches to the Eastern Front. It was the forerunner of, and remarkably similar to, modern teleoperated battlefield robots such as the U.S. Foster-Miller TALON (which was not deployed until six decades later, in 2000).

- The medium-sized Mittlerer Ladungsträger Springer was first deployed in 1944 (Fig. 6.195). Essentially it was a larger version of Goliath and was generally used operationally in very similar ways.

- The large Schwerer Ladungsträger Borgward B IV was first deployed in 1942 (Fig. 6.195). It served primarily as a reusable vehicle to remotely deliver demolition charges in vulnerable areas on the battlefield. Some models were also customized for other purposes, such as minesweeping and remote-controlled rocket-firing platforms.

While other countries were also experimenting with remote-controlled vehicles during World War II, the German systems were especially advanced, even including cameras (pp. 998, 5416) and remote-controlled weapons. They were used extensively during the war, and they were closely studied by other countries after the war, leading to modern robotic systems.

Some modern readers may object that these early German robots were teleoperated, but so are many modern robots such as battlefield units, bomb squad robots, aerial drones, and remote-controlled manipulator arms. Moreover, the German-speaking world simultaneously invented and demonstrated sophisticated computers (p. 1162) that could ultimately serve as “brains” to allow robots to function autonomously.

There were also numerous examples of both teleoperated and fully autonomous robotic vehicles among the variety of German torpedoes (pp. 1468–1473) and missiles (pp. 1144, 1254, and 1835) that were developed before and during World Wars I and II. Indeed, Allied press and intelligence reports of autonomously guided German missiles commonly referred to them as “robots” (e.g., pp. 5012, 4703, 5316, 5625, 5626).

Karl Saur (German, ca. 1901–1978, not to be confused with the Karl Saur who was a high-ranking government official under Albert Speer) and Rudolf Nebel (German, 1894–1978) invented, built, and used industrial robotics technology from the 1930s to 1945.[21] From 1937 onward, they designed and built customized industrial robots to perform tasks at a number of German companies. During 1944–1945, they built 20 industrial robots to assemble components at the underground Mittelwerk plant in Nordhausen. See Figs. 6.196–6.201.

In his autobiography, Rudolf Nebel summarized the history of his work on industrial robots with Karl Saur [Nebel 1972, pp. 147–153]:

[1937] Bei Siemens in Berlin hatte ich Diplomingenieur Karl Saur kennengelernt. Er hatte eine Maschine konstruiert, die ein Uhrwerk automatisch zusammenbauen konnte. Die Idee der Automation packte mich sofort, und ich entschloß mich, den Siemens-Konzern zu verlassen und mich mit Saur selbständig zu machen. Wir eröffneten ein Ingenieurbüro in Berlin-Wilmersdorf und entwickelten einen “Automatischen Arbeiter”, der zahlreiche Arbeitsvorgänge bewältigen konnte. Saur und ich entwarfen einen Prospekt, der den werbewirksamen Titel hatte: “1 Million Arbeitskräfte automatisch.” In einer Zeit, wo die Handarbeit noch das Maß aller Dinge war, wirkte unsere Broschüre geradezu sensationell. Als Anwendungsmöglichkeiten unserer Erfindung schlugen wir unter anderen vor:	[1937] At Siemens in Berlin, I met engineer Karl Saur. He had constructed a machine that could automatically assemble a clockwork. The idea of automation immediately grabbed me, and I decided to leave the Siemens group and start my own business with Saur. We opened an engineering office in Berlin-Wilmersdorf and developed an “automatic worker” that could handle numerous operations. Saur and I designed a brochure that had the promotional title: “1 Million Workers Automatically.” At a time when manual labor was still the measure of all things, our brochure had an almost sensational effect. As possible applications for our invention, we suggested, among others:
1. Montage von Maschinenelementen aller Art.	1. Assembly of all kinds of machine elements.
2. Gefährliche Arbeiten, wie Pulver pressen, Munitionsherstellung, Arbeiten mit Sprengstoff.	2. Dangerous work, such as [explosive] powder pressing, ammunition production, work with explosives.
3. Montage elektrischer Teile.	3. Assembly of electrical parts.
4. Bedienung einer Fließstraße von halbautomatischen Maschinen, einschießlich Transport der Werkstücke. Eine ganze Anzahl solcher Maschinen kann durch eine Steuergruppe bedient werden, und zwar in der Reihenfolge, daß die Maschinen ununterbrochen Arbeit leisten.	4. Operation of an assembly line of semi-automatic machines, including transport of workpieces. A whole number of such machines can be operated by one control group, in order that the machines perform work continuously.

Wir verschickten rund 1000 dieser Broschüren an alle Firmen, die 1937 mit Rüstungsaufträgen beschäftigt waren. Natürlich gab es Proteste von den Arbeitsämtern, die zu dieser Zeit noch rund 400 000 Arbeitslose in ihren Karteien hatten. Ein Arbeitsamtsdirektor bekam bei einer Besprechung einen Wutanfall und schrie mich an: “Sind Sie wahnsinnig geworden? Kaum haben wir die furchtbare Arbeitslosenzeit hinter uns, da fangen Sie mit Robotern an, dieses Elend wieder heraufzubeschwören!” Doch in anderen Dienststellen hatte man nicht die Sorge, daß unsere Erfindung soziale Schwierigkeiten bringen würde. Sogar die NSDAP war auf unsere Automaten aufmerksam geworden und überlegte, wie man die neuartige Maschine im Rahmen des Vierjahresplanes für die Rüstung nützen könne. [...]

Bis Kriegsausbruch arbeitete ich nun mit Saur zusammen an der Entwicklung des “Automatischen Arbeiters”. Wir bekamen Aufträge verschiedener Privatfirmen und konnten sorgenfrei leben, obwohl ich bei der Partei in Ungnade gefallen war. [...]

Ich konnte während der nächsten Kriegsjahre weiter an meinen Erfindungen arbeiten. In einer kleinen Werkstatt in Berlin-Lichterfelde erstellte Saur mit fünf Mitarbeitern die Konstruktion für die Automaten, deren Anfertigung, Montage und Arbeiten ich bei unseren Kunden überwachte.

We sent out about 1,000 of these brochures to all the companies that were busy with armaments orders in 1937. Of course, there were protests from the labor offices, which at that time still had about 400,000 unemployed in their files. One labor office director threw a tantrum at a meeting and shouted at me: “Are you out of your mind? No sooner are we past the terrible unemployment period than you start conjuring up this misery again with robots!” But in other departments, there was no concern that our invention would bring social difficulties. Even the Party had become aware of our automation and was considering how the novel machines could be used for armaments within the framework of the Four-Year Plan. [...]

Until the outbreak of the war, I worked together with Saur on the development of the “automatic worker.” We received orders from various private companies and were able to live without worries, even though I had fallen out of favor with the Party. [...]

I was able to continue working on my inventions during the years of the war. In a small workshop in Berlin-Lichterfelde, Saur and five employees designed the automated machines, whose production, assembly, and operation I supervised for our customers.

Wir konnten unsere Arbeiten bis November 1943 fortsetzen. Am 23. November 1943 wurde das Berliner Konstruktionsbüro total ausgebombt, und Saur und ich verlegten unsere kleine Firma nach Bad Wilsnack an der Elbe. Wenige Tage vor dem Attentat auf Hitler am 20. Juli 1944—die Deutsche Propaganda stellte in dieser Woche die ersten Einsätze der V 1 groß heraus—rief mich Klaus Riedel im Büro an. Wir sprachen kurz über Kriegslage, und dann machte mir mein alter Mitarbeiter einer interessanten Vorschlag. Riedel sagte, er habe mit den beiden Chefs des geheimen "Mittelwerkes" gesprochen und sei auf großes Interesse gestoßen. Ich solle sofort mit meinem Raketenfilm und den Unterlagen über den "Automatischen Arbeiter" nach Berlin kommen. Direktor Sawatzki und Generaldirektor Rickhey seien gerade in den Borsigwerken, und es könne sein, daß sie mir einen Auftrag erteilen würden. [...]

We were able to continue our work until November 1943. On 23 November 1943, the Berlin design office was totally bombed out, and Saur and I moved our small company to Bad Wilsnack on the Elbe. A few days before the assassination attempt on Hitler on July 20, 1944—German propaganda that week gave great publicity to the first missions of the V-1—Klaus Riedel called me at the office. We talked briefly about the war situation, and then my old co-worker made me an interesting proposition. Riedel said he had talked to the two chiefs of the secret "Mittelwerk" and had met with great interest. I should come to Berlin immediately with my rocket film and the documents on the "Automatic Worker." Director Sawatzki and General Director Rickhey were at the Borsig Works at the moment, and they might be willing to place an order with me. [...]

Bei der Besprechung mit Rickhey und Sawatzki bekam ich den Auftrag, im "Mittelwerk" 20 "Automatische Arbeiter" zu bauen, für die Saur von Bad Wilsnack auch die Konstruktionszeichnungen zu liefern hatte. Meine Maschinen sollten bei der Fertigung der Rudermaschine für die "V 1" verwendet werden. Ich bezog ein Büro in Halle 40 der unterirdischen Rüstungsfabrik. Unter meiner Aufsicht arbeiten einige deutsche Techniker und 100 Häftlinge Tag und Nacht an der Montage der Automaten. Mit den Häftlingen hatte ich praktisch nie Kontakt, da ich ständig zwischen Bad Wilsnack und Nordhausen pendelte.

At the meeting with Rickhey and Sawatzki, I received the order to build 20 "automatic workers" in the "Mittelwerk," for which Saur from Bad Wilsnack also had to supply the design drawings. My machines were to be used in the production of the rudder machinery for the V-1. I moved into an office in Hall 40 of the underground armaments factory. Under my supervision, several German technicians and 100 prisoners worked day and night on assembling the automated machines. I practically never had any contact with the prisoners, since I was constantly commuting between Bad Wilsnack and Nordhausen.

Although Nebel (or his publisher) wrote “V 1” in the passage above in his 1972 autobiography, the industrial robots appear to have been intended to work on V-2 (A-4 rocket) parts. They may have been designed to fashion the graphite exhaust deflectors that required careful machining and shaping from several directions.

Future scholars should investigate whether these wartime German robotics projects directly or indirectly influenced postwar work on robotics by George Devol or others, in view of considerations such as these:

- U.S. forces seized control of Mittelwerk and the surrounding areas in April 1945 and shipped huge amounts of hardware and documentation back to the United States, which probably would have included the 20 “automatic workers” and any related information. (For other examples of the widespread removal of production machinery, see pp. 2075–2086.)

- The United States also confiscated all wartime German patents such as Saur’s patents on industrial automation (pp. 1215, 2108–2113).

- Saur, Nebel, and the other robotics engineers were likely interrogated by U.S. technical investigators after the war (e.g., pp. 2124–2136).

OFFICE NATIONAL DE LA PROPRIÉTÉ INDUSTRIELLE.

BREVET D'INVENTION.

XII. — Instruments de précision, électricité.
7. — Applications générales de l'électricité.

N° 373.933

Procédé et appareil pour la commande à distance de moteurs et dispositifs analogues.

Société dite : FELTEN & GUILLEAUME LAHMEYERWERKE ACTIEN-GESELLSCHAFT et M. Anton FLETTNER résidant en Allemagne.

Demandé le 26 janvier 1907.
Délivré le 29 mars 1907. — Publié le 30 mai 1907.
(Demande de brevet déposée en Allemagne le 27 janvier 1906. — Déclaration des déposants.)

La présente invention a trait à la commande d'appareils, machines, etc., éloignés stationnaires ou en mouvement et cela sans fils conducteurs continus. D'après cette invention les signaux de contrôle et l'emploi d'impulsions télédynamiques d'espèces différentes sont rendus superflus, quels que soient le nombre et le genre des opérations à produire, par la disposition, au point de réception, d'un appareil préparant, en succession cyclique, les différentes connexions nécessaires à la production de ces opérations, de sorte que l'émission d'une impulsion produit, suivant le moment choisi, l'un ou l'autre des couplages et donne lieu, par conséquent, à l'une ou l'autre des opérations.

Le dessin schématique ci-joint représente, à titre d'exemple, l'application de l'invention à la commande du mécanisme de direction d'une torpille. Dans ce dessin, *a* représente le cohéreur qui, lorsqu'il est rendu conducteur par l'action d'ondes électriques, fait passer le courant de la pile *b* dans le relais électromagnétique *c*.

L'interrupteur à relais *e* est ainsi fermé et l'électro-aimant *f* reçoit pour la position de repos représentée du doigt *d*, le courant de la pile *g*, de sorte qu'il attire le verrou *h*; le disque *i* est donc libéré et tourne dans le sens de la flèche représentée, sous l'action d'un mouvement d'horlogerie ordinaire placé au-dessous de lui, jusqu'à ce que le verrou *h* tombe dans l'entaille *k* suivante de ce disque *i*. Ce dernier mouvement se produit sous l'action du ressort *l*, car le doigt *d* est entraîné à la position représentée en pointillé, lors de la rotation du disque *i* de 45° par exemple, par les chevilles *m* portées par ce disque *i*, le circuit *n o g e f* n'étant plus parcouru par le courant dès que le doigt *d* a abandonné le plot initial *n*.

Pendant la course du doigt *d*, on peut actionner, par des étincelles d'émission, l'appareil que l'on veut déclencher et commander par ondes électriques ou impulsions analogues.

On peut, par exemple, employer à cet effet la disposition suivante :

Quand le doigt *d* a dépassé le plot initial *n*, il arrive sur un des contacts *p* du frappeur, ce qui ferme le circuit comprenant l'auto-interrupteur *q* et la pile *r*, de sorte que le marteau *s* frappe le cohéreur *a*, lui enlevant ainsi sa conductibilité, ce qui fait que le circuit du cohéreur n'est plus parcouru par le courant et que l'interrupteur à relais *e* s'ouvre sous l'action du ressort *t*.

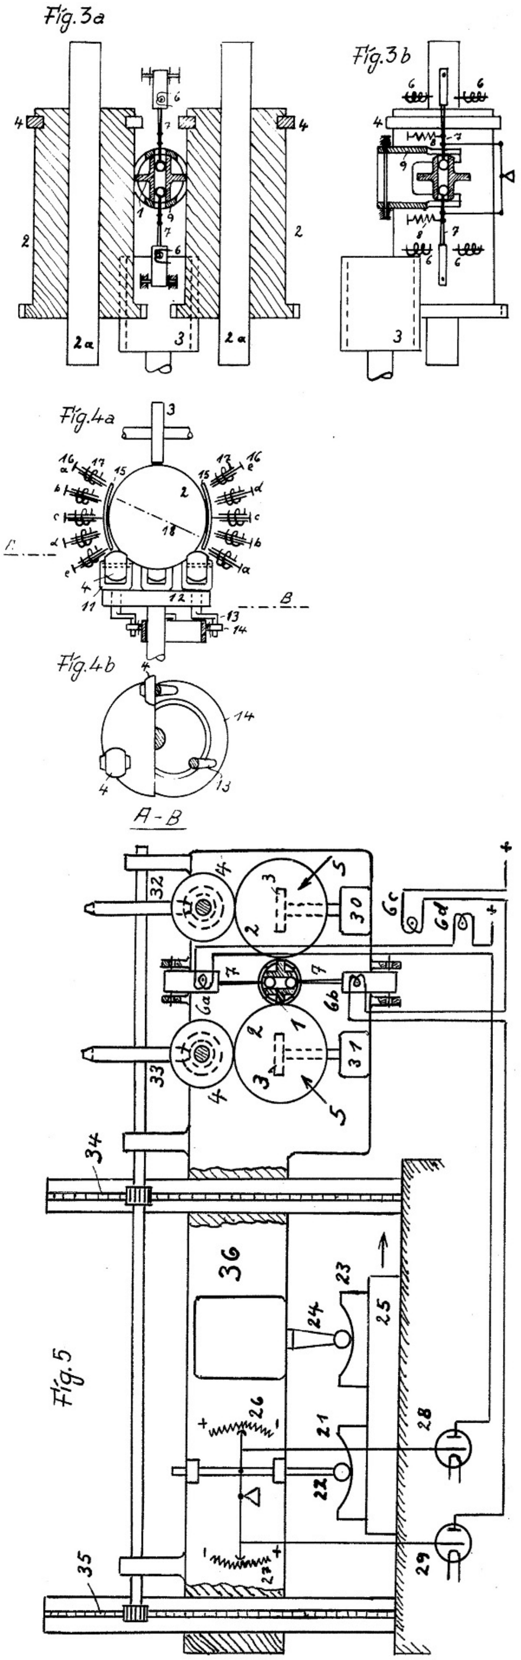
Steuervorrichtung für Reglungen und Steuerungen aller Art,
z. B. an Arbeitsmaschinen, u. a. Kopierfräsmaschinen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 8. Juni 1951 an
Patentanmeldung bekanntgemacht am 18. Juni 1953
Patenterteilung bekanntgemacht am 25. Februar 1954

Gegenstand der Erfindung ist eine Steuervorrichtung für Reglungen und Steuerungen aller Art, wie sie zur Konstanthaltung irgendwelcher Betriebsgrößen, zur Betätigung automatischer Arbeitsmaschinen, z. B. Kopierfräsmaschinen, dienen, aber auch als automatische Steuerungen von Fahrzeugen und ähnlichen Einrichtungen benutzt werden. In allen diesen Fällen lassen sich beliebige Steuerimpulse und Funktionen derselben leicht auf elektrischem oder fotoelektrischem Wege gewinnen und trägheitsfrei verstärken. Der Erfindungsgegenstand soll einem zu steuernden Element eine Geschwindigkeit erteilen, die einem derartigen, in vielen Fällen elektrischen, rasch veränderlichen Impuls entspricht. Es sind zahlreiche hydraulische, pneumatische, elektrische und mechanische Steuerungen bekannt, die einem solchen Zweck dienen. Damit die Geschwindigkeit möglichst trägheitslos einer Impulsänderung folgt, muß u. a. eine genügende Beschleunigungskraft zur Verfügung stehen und zu diesem Zwecke die Steilheit des Kraftanstiegs genügend groß sein, wenn man die Kraft oder das Drehmoment der Steuervorrichtung in Abhängigkeit von der Differenz zwischen Soll- und Istgeschwindigkeit aufträgt. Eine solche Steilheit weist nun ein jeder Antrieb auf, der auf Reibungsmitnahme beruht (trockene Reibung). Hierbei ergeben sich aber leicht gewisse Nachteile. Aus- und einschaltbare Kupplungen z. B., die auf Reibungsmitnahme beruhen, haben eine unstetige, intermittierende Arbeitsweise, die für viele Zwecke ungünstig ist. Reibradgetriebe bekannter Art benötigen große Verstellwege. Ein für alle Zwecke besser geeignetes Reibradgetriebe ist Zweck der Er-



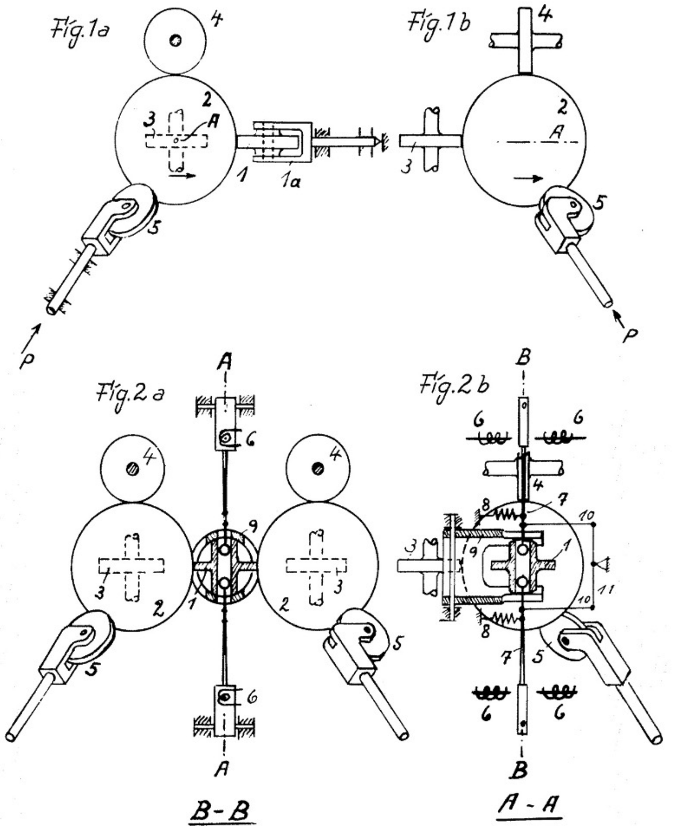


Figure 6.201: Karl Saur filed this patent on industrial robotics after the (West) German patent office reopened, but it appears to be directly based on his wartime work.

6.8 Radar and Sonar Technologies and Countermeasures

Creators from the German-speaking world invented, developed, and demonstrated:

6.8.1. Radar

6.8.2. Radar countermeasures

6.8.3. Microwave heating

6.8.4. Sonar

6.8.5. Sonar countermeasures

6.8.6. Ultrasound imaging

6.8.7. Acoustic weapons

6.8.8. Radio and acoustic proximity fuses and homing devices

6.8.1 Radar

German-speaking scientists invented radar at the beginning of the twentieth century and developed sophisticated radar systems for a variety of applications through World War II (and afterward in Allied countries).[22]

Nikola Tesla (Serbo-Croatian, educated in Austria, 1856–1943, p. 954) proposed radar in 1900, although as far as is presently known, he did not actually build a working system. Tesla biographer Margaret Cheney provided some details of Tesla's proposal [Cheney 1981, p. 208]:

> In the circumstances, it is not surprising that when Tesla first began to speculate about military applications of radar, it was with respect to locating ships and submarines rather than to detecting enemy bombers. Tesla had predicted the general concept of radar in his sweeping article for *Century* magazine of June 1900: "Stationary waves . . . mean something more than telegraphy without wires to any distance. . . . For instance, by their use we may produce at will, from a sending station, an electrical effect in any particular region of the globe; we may determine the relative position or course of a moving object, such as a vessel at sea, the distance traversed by the same, or its speed...."

The world's first working radar system was created and demonstrated by Christian Hülsmeyer (German, 1881–1957) in 1903, decades before the widespread adoption of radar technology by other countries (Fig. 6.202). David Pritchard extensively researched Hülsmeyer's life and inventions [Pritchard 1989, pp. 16–17]:

> [...] Hülsmeyer was promptly invited to demonstrate his equipment to the representatives of shipping companies. The *Kölnischer Zeitung* of 18 May 1904 carried the report:
>
> > The Telemobiloscope, an invention of engineer Christian Hülsmeyer, was demonstrated to representatives of Norddeutscher Lloyd and the Argo Shipping Company of Bremen and other invited gentlemen at the Dom Hotel yesterday morning at 11 o'clock. The discovery is based on the principle of wireless telegraphy and is intended to locate ships and other metallic objects at sea. The difference between the already existing employment of wireless telegraphy and this discovery is based on an exclusive and constructional change, in that wireless telegraphy employs a transmitter and receiver on separate ships but with the Telemobiloscope the transmitter and receiver are arranged on one and the same vessel. The electrical waves radiated from the transmitter cannot directly reach the receiver, but must be reflected from metallic objects on the sea, logically ships, and thus return to the receiver. The great advantage which the discovery offers lies above all in the fact that ships which are fitted with this system of transmitter and receiver can locate any other ship that does not carry the apparatus. Indeed, the captain on the bridge can be informed of the approach of another vessel and find its bearing up to a range of 5 kilometres, so that should his lights and fog signals fail to work he still has sufficient time to steer his ship on the correct course and thus prevent severe disasters in good time. Research with smaller apparatus calculated for shorter ranges have been perfectly successful. A company for the manufacture of the discovery has been formed under the title of The Telemobiloscope Company, Hülsmeyer and Mannheim.
>
> [...O]n Thursday, 9 June 1904, assisted by students of Delft University, Hülsmeyer assembled his equipment in the tender *Columbus* and cruised up and down Rotterdam Harbour detecting vessels at up to 5 kilometres' range with unerring accuracy. The only problem was that as eight technical representatives of foreign shipping companies were with him to witness the demonstration he was obliged to take out a similar number of foreign patents, and this cost more money.
>
> The representatives were however enthusiastic about the demonstration and showered Hülsmeyer with praise, and after a lecture in which he explained that even longer ranges were quite possible he waited for orders.

While Hülsmeyer was unable to find commercial customers for his new radar system, his public demonstrations, worldwide research contacts, press coverage, and numerous patents directly seeded and guided the further development and application of radar by many other people and organizations.

Hans Dominik (German, 1872–1945), an engineer who was better known for his science fiction stories (p. 1970), worked together with Richard Scherl (German, 18??–19??) to build and demonstrate another prototype radar system in 1915–1916.

Christian Hülsmeyer
(1881–1957)
invented radar in 1903

N° 25,608 **A.D. 1904**

Date of Application, 24th Nov., 1904—Accepted, 23rd Mar., 1905

COMPLETE SPECIFICATION.

Improvement in Hertzian-wave Projecting and Receiving Apparatus for Locating the Position of Distant Metal Objects.—

I, CHRISTIAN HÜLSMEYER, of 3 Grabenstrasse, Düsseldorf, Germany, Engineer, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

This invention has reference to an improved Hertzian-wave projecting and receiving apparatus for locating the position of distant metal objects such for example as ships, wrecks or submarine boats.

In the Specification of the British Patent No. 13170/1904, an apparatus is described which is intended to be used for indicating the presence of a metal body such as a ship, but such an apparatus only indicates the direction in which the metal body or object is situated. It would without doubt be most useful if it were possible to also ascertain at what distance from the point of observation the metal body is located, and the object of my invention is to enable such a result to be attained.

For this purpose I employ a projector which throws the electric waves in the form of a powerful cylindrical bundle & it is sufficient to move the projector up or down in a vertical plane (said projector having been first turned in the direction of the metal body) until the particular angle is found at which the action of the waves reflected from the metal body to the receiver is strongest. The angle which the projector at that time makes with the horizon is read off & by its aid the distance of the metal body can be easily calculated or ascertained from a prepared table. The movements of the various parts as well as the ascertaining of the correct angle may be accomplished in various ways of which I hereinafter describe two. In one of these the projector, containing the reflector *etc.*, whereby the electric rays are concentrated, is provided with an adjustable weight whereby the projector, which is appropriately mounted, is inclined. In the other form, I project parallel rays by means of a pair of lenses, which latter are adapted to be moved relatively to the projector casing, whereby the angle of inclination of the wave beams to the horizontal can be varied.

In the accompanying drawings the two methods of altering or adjusting the angle of the rays are shown diagrammatically.

Figure 6.202: Christian Hülsmeyer invented and demonstrated radar in 1903.

One obstacle to the first radar systems was the military focus during World War I on trench warfare, which was not particularly in need of a technology such as radar. However, by the end of World War I, it became clear that aircraft and submarines would play key roles in future wars, providing a strong military incentive to develop radar systems that could be used against or by such vehicles.

The first radar systems had relatively little power, which meant that their radio waves could not travel very far, reflect off an object, and return without being too weak to detect. A solution to that problem was developed in 1920 by Heinrich Barkhausen (German, 1881–1956) and Karl Kurz (German, 1881–1960). They invented the 300–400 MHz Barkhausen-Kurz oscillator, which enabled high-frequency, high-power radar systems (Fig. 6.203).

An alternative approach that enabled high-power radar systems was the magnetron. As shown in Fig. 6.204, Hans Gerdien (German, 1877–1951) invented and patented the first magnetron in 1910. By 1924, Erich Habann (German, 1892–1968; see also p. 1060) and August Žáček (Czech/Austrian, 1886–1961; see also Section 6.5.10), working independently, had improved the performance of magnetrons to enable them to produce frequencies up to 1 GHz. In 1935, Hans Erich Hollmann (German, 1899–1960) invented, demonstrated, and patented the cavity magnetron, which used multiple cavities within a metal block to achieve very high frequencies and power levels (Fig. 6.205).

With the move toward German rearmament, several German companies began developing sophisticated radar systems in the early 1930s (Figs. 6.206–6.207). In January 1934, Rudolf Kühnhold (German, 1903–1992) of the government Nachrichtenmittel-Versuchsanstalt (NVA, Navy Transmissions Laboratory) supported Paul-Günther Erbslöh (German, 1905–2002) and Hans-Karl von Willisen (German, 1906–1966) in founding GEMA (Gesellschaft für Elektroakustische und Mechanische Apparate) to produce radar and sonar systems. Kühnhold led the development at NVA and GEMA of the Freya long-range radar, which was first demonstrated in early 1937.

At the rival Telefunken company, Wilhelm Runge (German, 1895–1987, son of the mathematician Carl Runge, p. 833) led the development of the Würzburg-Riese short-range radar, which was also first demonstrated in 1937. Some radar experts such as Hans Erich Hollmann worked on both the GEMA and Telefunken radar programs [www.radarworld.org/germany.html]. (After World War II, Hollmann moved to the United States and improved radar systems there [www.radarworld.org/hollmann.html].)

In fact, the initially rival GEMA Freya and Telefunken Würzburg-Riese radar systems ended up working very well together, since Freya could track targets at long ranges and Würzburg-Riese could provide more accurate location information at short ranges. Thus Freya and Würzburg-Riese systems were often located together (Fig. 6.208), and they were widely and effectively used throughout World War II against Allied air raids.

Creators such as Johannes Plendl (German, 1900–1991) also developed a variety of airborne radar systems, of which X-Gerät was probably the best known.

The traveling wave tube (TWT) was an important invention for radar as well as other transmission systems. A TWT combines aspects of a vacuum tube amplifier, a cathode ray tube, and a cavity magnetron into one complex device. Its unique design allows it to amplify radio and microwave signals over a wide spectrum up to frequencies of tens of gigahertz (GHz) and with powers up to tens of kilowatts (kW). Because of this combination of properties, a TWT can simultaneously send a very large number of signals at different frequencies with enough power to be received over very long distances. As such, TWTs are useful for transmitting not only complex and powerful radar signals, but also microwave communications beams carrying many different simultaneous audio, visual, and/or data channels. TWTs are widely used even today, since it has been difficult to create reliable solid state devices with the necessary combination of extreme properties.[23]

According to officials histories, Rudolf Kompfner (Austrian, 1909–1977, Fig. 6.209) first conceived of TWTs while he was a refugee in the United Kingdom during World War II, and he built the first fully functional TWTs in the early 1950s after he had been transferred to AT&T Bell Laboratories. Kompfner went on to have a long and productive career at Bell Labs.[24]

There is evidence that another team of German-speaking creators designed and demonstrated TWTs and transferred that technology to Bell Labs, all earlier than Kompfner did (Figs. 6.207 and 6.210–6.211). From the currently available archival and published documents, Herbert Schnitger (German, 19??–19??), Dieter Weber (German, 19??–19??), and their associates appear to have invented and demonstrated TWTs in Germany during the war, especially for the purpose of sending multiplexed control signals back and forth between ground stations and long-range missiles. In July 1945, the U.S. Army evacuated Schnitger, Weber, some of their other team members, and their equipment and documents from Thuringia ahead of the Russian occupation. In September 1945, an investigator from the Western Electric division of American Telephone & Telegraph (AT&T) expressed great interest in Schnitger and requested that he, his equipment, and his information be transferred to the United States. Then in July 1946, AT&T suddenly announced that it had just "invented" a revolutionary new device—the traveling wave tube. Schnitger and Weber seem to have lapsed into obscurity while AT&T achieved great fame and fortune with their work. For more details, see pp. 2938–2962.

Historians should thoroughly investigate the details of the wartime Schnitger-Weber work, its postwar transfer, and whether and how the wartime/postwar Schnitger-Weber and Kompfner research programs were interrelated.

Reinhold Rüdenberg (German, 1883–1961), an innovator in many areas of electrical engineering, emigrated from Germany to the United States in the 1930s. In the 1940s, he developed phased-array radar systems, as shown in Fig. 6.212.

'UNITED STATES PATENT OFFICE.

HANS GERDIEN, OF HALENSEE, NEAR BERLIN, GERMANY, ASSIGNOR TO SIEMENS & HALSKE, A. G., OF BERLIN, GERMANY, A CORPORATION OF GERMANY.

CURRENT-RELAYING APPARATUS. BEST AVAILABLE CO

1,004,012. Specification of Letters Patent. Patented Sept. 26, 1911.

Application filed January 7, 1911. Seria! No. 601,443.

To all whom it may concern:

Be it known that I, Hans Gerdien, a subject of the German Emperor, and residing at Halensee, near Berlin, Germany, have invented certain new and useful Improvements in Current-Relaying Apparatus, of which the following is a specification.

The subject-matter of my invention is means for producing great changes of energy in dependence on smaller changes of energy, the great changes of energy being to a certain extent proportional to the smaller changes of energy. Such means may be designated a quantitative relay in contradistinction to customary relays, in which the secondary changes of energy brought about by primary changes of energy are in no definite relation one to the other.

My means are particularly suitable for increasing the action of arriving waves in radiotelegraphy, for increasing the action of telephones, the action of telegraphs in cable telegraphy, for signaling, and for controlling machines from a distance, and the like.

According to my invention, for producing the great changes of energy a luminous discharge is used, whose strength is influenced by a magnetic field varied by small primary changes of energy. By luminous discharge is to be understood the electric current in a gas, in which the material of which the cathode is composed is not vaporized by the current and does not participate in the transmission of the current. In contradistinction thereto an arc is formed only when the material of which the cathode is composed is vaporized by the current.

Cathode rays are a constant accompanying phenomenon of luminous discharge. They are the carriers of a certain fraction of the luminous discharge and are that part of the whole luminous discharge which can be magnetically or electrically most readily influenced in its position and direction. In my present invention, however, the energy of the total luminous discharge, and not only the position and direction of the cathode rays, is directly influenced by a magnetic field.

Several illustrative embodiments of my invention are diagrammatically represented by way of example in the accompanying drawing, wherein:—

Figure 1 shows the simplest form of my invention; Figs. 1^a, 1^b and 1^c are sections through various vacuum tubes showing the course of the cathode rays under various conditions; Fig. 2 shows an embodiment similar to that shown in Fig. 1 but with the addition of an auxiliary circuit; Fig. 3 is a diagram; Fig. 4 shows another embodiment of my invention; Figs. 5 and 5^a show modified forms of vacuum tubes in sectional elevation; Figs. 5^b and 6 are sections through the tube shown in Fig. 5^a, and through a modified form of tube, respectively; Fig. 7 shows another embodiment of my invention, and Fig. 8 shows how my invention may be used in connection with radiotelegraphy.

Referring firstly to Fig. 1, *a* designates a closed glass tube containing a highly rarefied gas; *b* designates the cathode, *c* the source of current, *d* the anode, *e* the conductor connecting the electrodes to the source of current, and *s* a receiving apparatus, *e. g.* a telephone, interpolated in this conductor. These members form the secondary circuit. The primary circuit consists of the coil *f* mounted concentrically relatively to the cathode *b*, a sender *p*, *e. g.* an alternating current generator, and the conductors *r* connecting the sender with the coil *f*. By showing part of the conductors *r* in dotted lines it is intended to indicate that the sender *p* may be at a great distance from the coil *f*. When the coil *f* is currentless, cathode rays will go from the cathode *b* at right angles to the surface of the rod, *i. e.* radially, to the wall of the tube, as shown in Fig. 1^a. In this figure *a* designates the tube, *b* the cathode rod and *k* the cathode rays. If, on the contrary, a current traverses the coil *f*, the cathode rays are deflected and arranged curved around the cathode rod *b*, as shown in Fig. 1^b. When the field of the coil *f* is increased still more, the cathode rays no longer arrive at the wall of the tube at all, but are caused to arrange themselves in circles about the cathode, as represented in Fig. 1^c. As soon as the cathode rays are curved, the intensity of the total luminous discharge is simultaneously changed. To what this is due, is very difficult to determine; probably it is due to the cathode rays traversing within the tube a longer path in consequence of their being curved around the rod so that the gas in the tube is consequently more highly ironized, whereby an increase of strength of the total luminous discharge is caused. To every change of

MAGNETRON

Hans Erich Hollmann, Berlin, Germany, assignor to Telefunken Gesellschaft für Drahtlose Telegraphie m. b. H., Berlin, Germany, a corporation of Germany

Application November 27, 1936, Serial No. 112,977
In Germany November 29, 1935

1 Claim. (Cl. 250—27.5)

My invention relates to electron discharge devices, more particularly to improvements in so-called magnetrons in which the electrode system is positioned in a magnetic field.

Investigations regarding the oscillation mechanism of magnetrons have shown that in a magnetron tube whose anode cylinder is divided by two or more slots into two or more segments, two different forms of oscillations of ultra short waves appear, in accordance with the chosen operating conditions, i. e. plate potential and strength of the magnetic field, and in accordance with the tuning of the outer resonance circuits connected to the segments. In one form of oscillation there is to be dealt with rotations of space charges produced by the action of the electrical field and the magnetic field extending at right angle to each other. This form of oscillation is not only attainable in a split anode magnetron, but also in a solid anode cylinder magnetron, and extends in the present state of the art downwards to waves of about one centimeter. The other type of oscillation has its actual origin in a negative electron resistance produced between the plate segments, and which excites the oscillatory system connected with the segments. The production of such negative electron resistance is to be found in the screw shaped course of the electron movement, such as result from the action of the radial and tangential electrical fields in the vicinity of the separation gaps of the segments in conjunction with the magnetic field extending substantially in the axial direction. This form of oscillation although not attaining the aforementioned high frequency owing to the natural inertia of the electron movement, produces however at 2 to 4 times longer waves a very much higher useful energy and a much more favorable efficiency.

The object of my invention is to provide an electrode arrangement and connection for a magnetron for increasing its efficiency.

To increase the efficiency and use of the energy of a magnetron I divide the plate cylinder into several segments, and so combine the segments that the negative electron resistances existing between the separating gaps of the segments, operate in parallel. However this can apparently only be assured when the high frequency potentials at all adjacent segment edges are of opposite phase. In order to secure this optimum state of oscillation of the segments, in the hitherto used structures of magnetron transmitters the segments situated diametrically opposite each other are connected together in pairs by means of one or several bent wire straps reaching around the plate cylinder. In a four part anode, two pairs of segments are obtained in this way each of which is connected to a pole of the resonance circuit to be excited.

When arriving at increasingly shorter waves, the natural frequencies of the small resonance circuits in the tube proper, and which are formed by the mutual capacity of the opposite segments, and the induction of the corresponding closing bend or connecting conductors, cause considerable disturbance, the more so since the connecting conductors when reaching at the outside around the anode cylinder must have a definite minimum length. Waves that are shorter than those which correspond to those small resonance systems thus either cannot be produced at all with such a tube, or only at a very poor useful effect.

Another drawback of these hitherto ordinary constructions of the anode segment system is to be seen in the fact that for instance with a four split anode, segments arranged diametrically opposite to each other have opposite high frequency potentials. This signifies however, that two adjacent segments have equal alternating potentials, and that the split portions situated between them cannot participate in the production of oscillations. Only the edges of the segments on both sides of the other two split portions actually carry opposite potentials and they alone must effect the excitation. Thus the tube is only unilaterally exploited and in an entirely incomplete manner.

By means of the arrangement of the connecting conductors described in the present invention, these drawbacks, namely the excessive length of the conductors as well as the various inclusions of the existing negative electron resistances in the building-up mechanism are safely eliminated. To this end, the invention is based upon the principle joining two adjacent segments by means of connection straps instead of connecting segments situated diametrically opposite to each other.

The novel features which I believe to be characteristic of my invention are set forth with particularity in the appended claim, but the invention itself will best be understood by reference to the following description taken in connection with the accompanying drawing in which Figure 1 is a diagrammatic transverse section of an electron discharge device embodying my invention, Figure 2 shows a detail of construction, and Figure 3 is a perspective of the mount shown in Figure 1 with a part broken away to show details of construction.

All of the four segments S_1 to S_4 around cath-

2 2,123,728

ode C are connected with each other by four conductors B_1 to B_4, whereby these conductors act, as previously, as inductances, and form small resonance systems with the mutual capacities of the segments. Electrode elements are mounted within an envelope E surrounded by the coil M for inducing a magnetic field parallel to the electrode elements within the envelope. Now when considering the incidental values of the high frequency potentials distributed over the segments, it can be seen that in fact all adjacent segments must oscillate in opposite phase, since at the ends of the bent straps or conductors, only voltages having opposite phase can appear when said ends oscillate in their natural frequency. When considering the electrode assembly, and hence also the state of oscillation as being completely symmetrical, oscillation anodes will be produced on all four culmination points *k* of the conductors. This means, that the inductance of the two adjacent conductor branches up to the culmination points, is to be considered as being placed in parallel to the inductance of each individual strap or conductor.

The arrangement must obviously not necessarily be such that, as indicated in the figure, the points at which the two connections meet the segment, coincide, the points may also be apart from each other, for instance moved towards the edges of the segments. Furthermore, if especially high frequencies are to be produced, it may eventually be of advantage, instead of passing the straps along the outside of the plate cylinder, to arrange them in the extended outer cylindrical surface in which the anodes are situated, and where they can be maintained much shorter. Such bent connections may also be arranged on both sides of the plate cylinder or segments.

In accordance with a further proposition, in place of the wire straps, sheet metal strips may be used to advantage, having the same width as the length of the electrode system for instance. The cross section through such a rosette shaped system remains thereby unchanged as indicated in the figure. The technical construction is especially simple if each strap forms a single piece with the two halves of the adjacent segments, and if the piece is riveted or welded at the bent edges, to the straps on both sides. Such structural part consisting of a strap and two segment halves thus has the cross section shown in Figure 2, and is joined to the following part at the edges *a*. Such sheet metal strips not only have the advantage of very low damping losses, but assure furthermore a uniform state of oscillation of the segments, and prevent undesirable longitudinal oscillations while assuring at the same time a favorable heat delivery, and high load capacity of the tubes.

In order to still further enhance the heat delivery, the straps may be formed as hollow bodies and have a suitable cooling means flow through them. Since the entire system is closed in itself, the cooling fluid may be suitably introduced for instance at the lower culmination point (see Figure 1) from where it will be branched towards the right and the left, and caused to leave at the upper culmination point. The principle of the construction of the segment set in accordance with the invention and relating to the high frequency part has no influence upon the other structures of the generator dealing with measures known as such, as for instance end plates maintained at suitable potential, or several filaments.

While I have indicated the preferred embodiments of my invention of which I am now aware and have also indicated only one specific application for which my invention may be employed, it will be apparent that my invention is by no means limited to the exact forms illustrated or the use indicated, but that many variations may be made in the particular structure used and the purpose for which it is employed without departing from the scope of my invention as set forth in the appended claim.

What I claim as new is:

An electron discharge device having a straight cathode, a plurality of pairs of sheet metal anode segments coextensive with each other and surrounding said cathode, conductors connecting adjacent anode segments, said conductors comprising sheet metal straps equal in width to the length of said anode segments, and means for producing a magnetic field parallel to said cathode.

1

The present invention relates to electronic amplifying devices and methods.

More particularly the invention concerns travelling wave tubes in which a desired signal may be amplified by an energy interchange between an electron beam and a radio-frequency signal.

It is an object of the invention to provide an amplifying device having an electron beam and a wave which alternately act and react on each other.

It is an object of the invention to provide an amplifying device which is efficient to convert D. C. power to radio frequency power over a wide frequency range.

It is an object of the invention to provide an amplifier which will operate over a wide range of frequency.

It is an object of the invention to eliminate resonant circuits in an amplifier to yield a satisfactory gain over a wide range of frequency.

It is an object of the invention to provide a microwave amplifier which is sensitive and gives a reasonably uniform response over a wide range of frequency.

It is an object of the invention to provide means for the velocity modulation of an electron stream.

It is an object of the invention to provide an electron stream and a modulated wave which move in the same direction and in such relation that the wave increases in amplitude as it moves.

It is an object of the invention to velocity modulate an electron stream and thereby to induce an electromagnetic wave in a transmission line, the wave being propagated along the line.

Other objects, purposes and applications of the invention will appear as the specification proceeds.

Because of conflicting requirements which are mutually incompatible, the drift-tube type of high sensitivity microwave amplifier or klystron, yields an unsatisfactory energy transfer at the gaps which energy modulate the electron beam if operation is required over a wide frequency range.

In accordance with the present invention use is made in an electronic discharge device of interaction between travelling electric fields and an electron stream to produce amplification of high-frequency signals. Such a structure, which may be termed a retarded wave device, may comprise a conductor which provides a high-frequency energy path between two points longer than the straight line joining them, for example a helix, so that the component of velocity in a direction parallel to the said straight line of fields induced by an electromagnetic wave travelling along said path is reduced to a fraction of the velocity of said electromagnetic wave along said path, and

2

an electron beam which passes adjacent said path, in a direction parallel to the straight line joining the two aforementioned points with a velocity of the same order as that of the aforementioned component of velocity of the fields induced by the travelling electromagnetic wave. The helical high-frequency energized coil referred to may be used to energy-modulate a group of ions in a mixed stream of ions so as to separate the lighter from the heavier, the latter passing through to a collector. The term energy-modulation as here used includes density modulation or "bunching" and velocity modulation.

In investigating the energy transfer between electron beams and electric fields or waves it appeared that their velocities should not differ too greatly. As electron beams which may conveniently be used in these devices travel at but a fraction of the speed of light, an electron beam accelerated by 2500 volts attaining a speed of about one tenth that of light, a loaded transmission line was employed to reduce the rate of propagation of the wave. The embodiments described successively below are set forth as examples and are not to be taken as limiting. They are illustrative only.

For such a line a helix of copper wire was used as the inner conductor and a brass tube as the outer conductor. A coaxial line suitable to work with a beam having a speed of about one tenth that of light was made of No. 18 standard-wire gauge copper wire, with an attenuation of two decibels per meter and an impedance of 500 ohms. Power can be readily put into and taken from such a structure by any of the known transforming methods.

A signal of 3000 megacycles was applied to the input end of the helix. With a beam current of one milliampere and a beam voltage of 2440 volts the radio-frequency output increased almost half as much again as when no beam was used. When the beam voltage was decreased there was a substantial loss of output, amounting to forty per cent at a beam voltage of 2200 volts.

With the above experimental information the factors for the construction of an amplifier having a good signal-to-noise ratio (as defined by the noise factor N) and a wide frequency band are at hand.

A helix of about sixty-six centimeters long and of No. 18 standard-wire gauge copper wire, wound on a quarter-inch mandrel, six turns/cm., was placed inside a long glass tube vacuum envelope. The beam voltage was set at 1830 volts and the effective wavelength within the tube was 7.7 millimeters. Due to losses in the copper and glass as well as imperfectly matched impedances the cold

TRAVELING WAVE TUBE

Rudolf Kompfner, Far Hills, N. J., assignor to Bell Telephone Laboratories, Incorporated, New York, N. Y., a corporation of New York

Application May 14, 1953, Serial No. 355,028

20 Claims. (Cl. 315—39.3)

This invention relates to coupled helices and more particularly it relates to the incorporation of such helices in traveling wave tubes.

An object of this invention is to provide an improved means for inserting attenuation into the wave propagating circuit of a traveling wave tube.

Amplification in a traveling wave tube may be obtained by propagating an electromagnetic wave along a slow wave circuit which is in coupling relation to an electron stream so that the wave may then extract energy from the electrons. In what is probably the most common type of traveling wave tube, a wave is conducted along a helix coaxial with an electron stream so that the axial component of the wave travels in the direction of electron flow at substantially the same velocity as the electrons. There may exist in this kind of tube, however, in addition to the forward wave, backward traveling waves which are capable of returning sufficient energy to the input of the circuit to sustain oscillations. Because these oscillations reduce tube efficiency and produce other bad effects it is frequently very desirable to prevent their occurrence and to this end it is customary to introduce loss along the helix whereby any backward traveling wave which may be present is reduced in amplitude below that necessary to produce oscillations. Previous to this invention, various ways, such as coatings of resistive material in the vicinity of the helix, have been developed to provide this loss, but so far as is known none of them has been able to provide uniform loss over a broad frequency band while at the same time permitting external adjustment of the amount of loss or its location along the helix. The present invention through the use of coupled helices is designed to provide these advantages.

In accordance with the present invention and in one embodiment thereof, the wave propagating helix of a helical traveling wave tube is coupled to a concentric surrounding helix so that unwanted wave energy may be extracted from the tube. This energy, which might otherwise cause spurious oscillations in the tube, is then dissipated in a resistance connected to the outer helix. Moreover, by making the diameter and pitch of this helix in particular ratios, respectively, to the diameter and pitch of the inner helix, the efficiency and band width for the tube may be improved.

A more complete understanding of the nature of this invention, however, will best be gained from a study of the following detailed description given in connection with the accompanying drawings in which:

Fig. 1 is a side view of a helical traveling wave tube having external concentric helices energy coupled to the wave propagating helix;

Fig. 2 shows a structure similar to that in Fig. 1 in which the wave propagating helix is coupled to one external helix having a resistance termination at each end, and to a second external helix which forms a part of the output circuit; and

Fig. 3 is a plot of the phase constant β_b of the "beat" wave on coupled helices, such as shown in Figs. 1 or 2,

2

as a function of the phase constant β of a wave on the inner helix when separate from other elements for various ratios of inner to outer helix radii.

Referring now in particular to the drawings, Fig. 1 is an illustrative embodiment of a traveling wave tube **10** having a helical wire transmission circuit **11**. This helix is adapted so that a high frequency signal applied to the circuit at the gun end of the tube propagates along the circuit being amplified in its course by interaction with the electron stream **12** which passes through the center of the transmission helix. At the collector end of the tube the amplified signal is then extracted by an appropriate output circuit. External helices **13** and **14** are wrapped concentrically around helix **11** so that they may extract wave energy from the circuit and thus attenuate the signal voltage in the region near them. They are conveniently, but not necessarily, wrapped upon glass or quartz envelope **15** so that they may readily be moved along the axis of the tube. One end of each helix is formed into a pancake spiral substantially as shown so that resistance material **16** may be inserted in the space between or including the spirals.

The winding sense of helix **13** or helix **14** depends upon the amount of coupling desired; winding in a direction opposite to that of the winding of helix **11**, produces greater coupling between inner and outer helices than produced by winding in the same sense. The outer helices should each have a turn pitch that makes the axial phase velocity of a wave propagating along each when it is separated from the inner helix approximately the same as the axial phase velocity on the inner helix. Since the axial phase velocity depends upon the length of conductor per unit of axial length, the phase velocities of the inner and outer helices when separated will be approximately the same when the turn pitches (angular pitches of conductor turns with respect to the axis of the helix) are the same. The ratio of inner to outer helix radii for a given frequency should be determined from Fig. 3 or Equation 6 herein, and when so chosen the attenuation introduced into tube **10** by helix **13** or helix **14** will be substantially constant over a wide range of frequency.

As a signal wave travels down helix **11** it induces on helix **13** or helix **14** a standing wave of voltage. For a wave traveling in the increasing z direction, which for convenience is taken from left to right, this voltage, which will appear on helix **13**, may be written

$$V_2=e^{j\omega t}e^{-\Gamma z} \qquad (1)$$

where Γ is the propagation constant. Assuming that the axial phase velocity along each helix separate from the other is the same, that the attenuation is zero, and that

$$\frac{X_{12}^2}{X_1X_2}=x^2\ll1;\ \frac{B_{12}^2}{B_1B_2}=b^2\ll1 \qquad (2)$$

where X_1 and X_2 are the series reactance per unit length, B_1 and B_2 are the shunt susceptance per unit length of the inner and outer helices respectively, and X_{12} and B_{12} are the mutual reactance and suspectance respectively between the helices, V_2 can be written

$$V_2=e^{j\omega t}\sin\left[\frac{\beta}{2}(x+b)z\right]e^{-j\beta\left(1+\frac{xb}{2}\right)z} \qquad (3)$$

where β, the phase constant of a wave on the inner helix, equals $\sqrt{B_1X_1}$. Thus the wave resulting from coupling two helices propagates with a velocity only slightly different from that of the wave on an uncoupled helix, but its amplitude varies sinusoidally, with distance, exhibiting a phenomenon which may be called "spatial beating." The "beat" phase constant is

$$\beta_b=\frac{\beta}{2}(x+b)$$

Untersuchungen über selbsterregte Schwingungen in der Wanderfeldröhre

Von Herbert Schnitger und Dieter Weber

(Mitteilung aus dem Fernmeldetechnischen Zentralamt)

Inhalt

An üblichen Wanderfeldröhren (traveling-wave tubes) werden ohne äußere Schaltmittel sehr gut definierte, kräftige Schwingungen zwischen 5 und 50 cm beobachtet. Es lassen sich Schwingbereiche festlegen, deren mittlere Wellenlänge mit der Spannung wächst. Der Wellenlängenanstieg kann an einer Röhre bis zu 1:3 betragen bei fast gleich großer Spannungserhöhung. Innerhalb eines Schwingbereichs fällt die Wellenlänge schwach mit der Spannung: bei z. B. 24,8 cm beträgt die Frequenzänderung etwa 50 kHz pro Volt. Die erhaltenen Ergebnisse werden unter Benutzung der Theorie von J. R. Pierce diskutiert. Versuche mit Röhren, bei denen sich die Wendel außerhalb des Glaskolbens befindet, weisen auf die Möglichkeit einer noch einfacheren Variation der Wendeleigenschaften hin.

Im Jahre 1946 berichtete Kompfner [1] erstmalig über die Wanderfeldröhre (traveling-wave tube), die eine neuartige Laufzeitröhre für das Dezimeter- und Zentimetergebiet darstellt. 1947 veröffentlichte dann Pierce [2] eine umfassende Theorie, die die wichtigsten Eigenschaften dieser Röhre mit meist guter Annäherung wiedergibt. Der hier vorliegende grundsätzlich neue Mechanismus einer Wechselwirkung zwischen Welle und Elektronenstrahl und die überraschend guten Ergebnisse, die Kompfner bereits mit den ersten Verstärkerröhren dieser Art erzielte, regten schnell zu verhältnismäßig zahlreichen weiteren Untersuchungen an [3 bis 12]. Der experimentelle Anteil dieser Arbeiten ist aber noch nicht sehr umfangreich. Eigene Untersuchungen zeigten uns, daß z. B. der Bau von Verstärkern sehr durch eine leicht einsetzende Selbsterregung erschwert wird. Diese Selbsterregung wurde von Kompfner bereits erwähnt, aber nicht näher beschrieben. Um die Selbsterregung systematisch unterdrücken zu können, schien es uns daher zweckmäßig, sie experimentell zu untersuchen. Die erhaltenen Ergebnisse, über die im Folgenden berichtet wird, sind auch für die Theorie der Wanderfeldröhre, insbesondere für die Berechnung der Eigenschaften der Wendeln, interessant. Einige Besonderheiten des Schwingungsmechanismus könnten ferner dazu führen, daß die Wanderfeldröhre trotz ihres vorerst noch geringen Wirkungsgrades und des zur Zeit noch großen Aufwandes eine gewisse Bedeutung als Oszillatorröhre erhält, so z. B. für Meßsender mit besonderen Anforderungen, wie sie etwa die Einstellung der Frequenz über mehrere Oktaven durch ausschließliche Änderung einer Gleichspannung darstellt.

Aufbau und Funktion der Wanderfeldröhre

Den Aufbau der für die Messungen benutzten Wanderfeldröhren zeigt Bild 1. Die Röhre besteht aus zwei Hauptteilen: Der Elektronenspritze und der Wendel. Die Elektronenspritze erzeugt einen fadenförmigen Elektronenstrahl homogener Geschwindigkeit v_0, der die Wendel in Richtung der Achse durchläuft. Läßt man eine Welle auf der Wendel entlanglaufen, dann bewirkt die schraubenartige Struktur

NEW TUBE EXPANDS RADIO POSSIBILITIES

Device Can Send 10,000 Phone Calls at Once, 100 Million Wired Words a Minute

---

WIDENS TELEVISION FIELD

Old Broadcast Band Enlarged 800 Times and Improves Service in Accordance

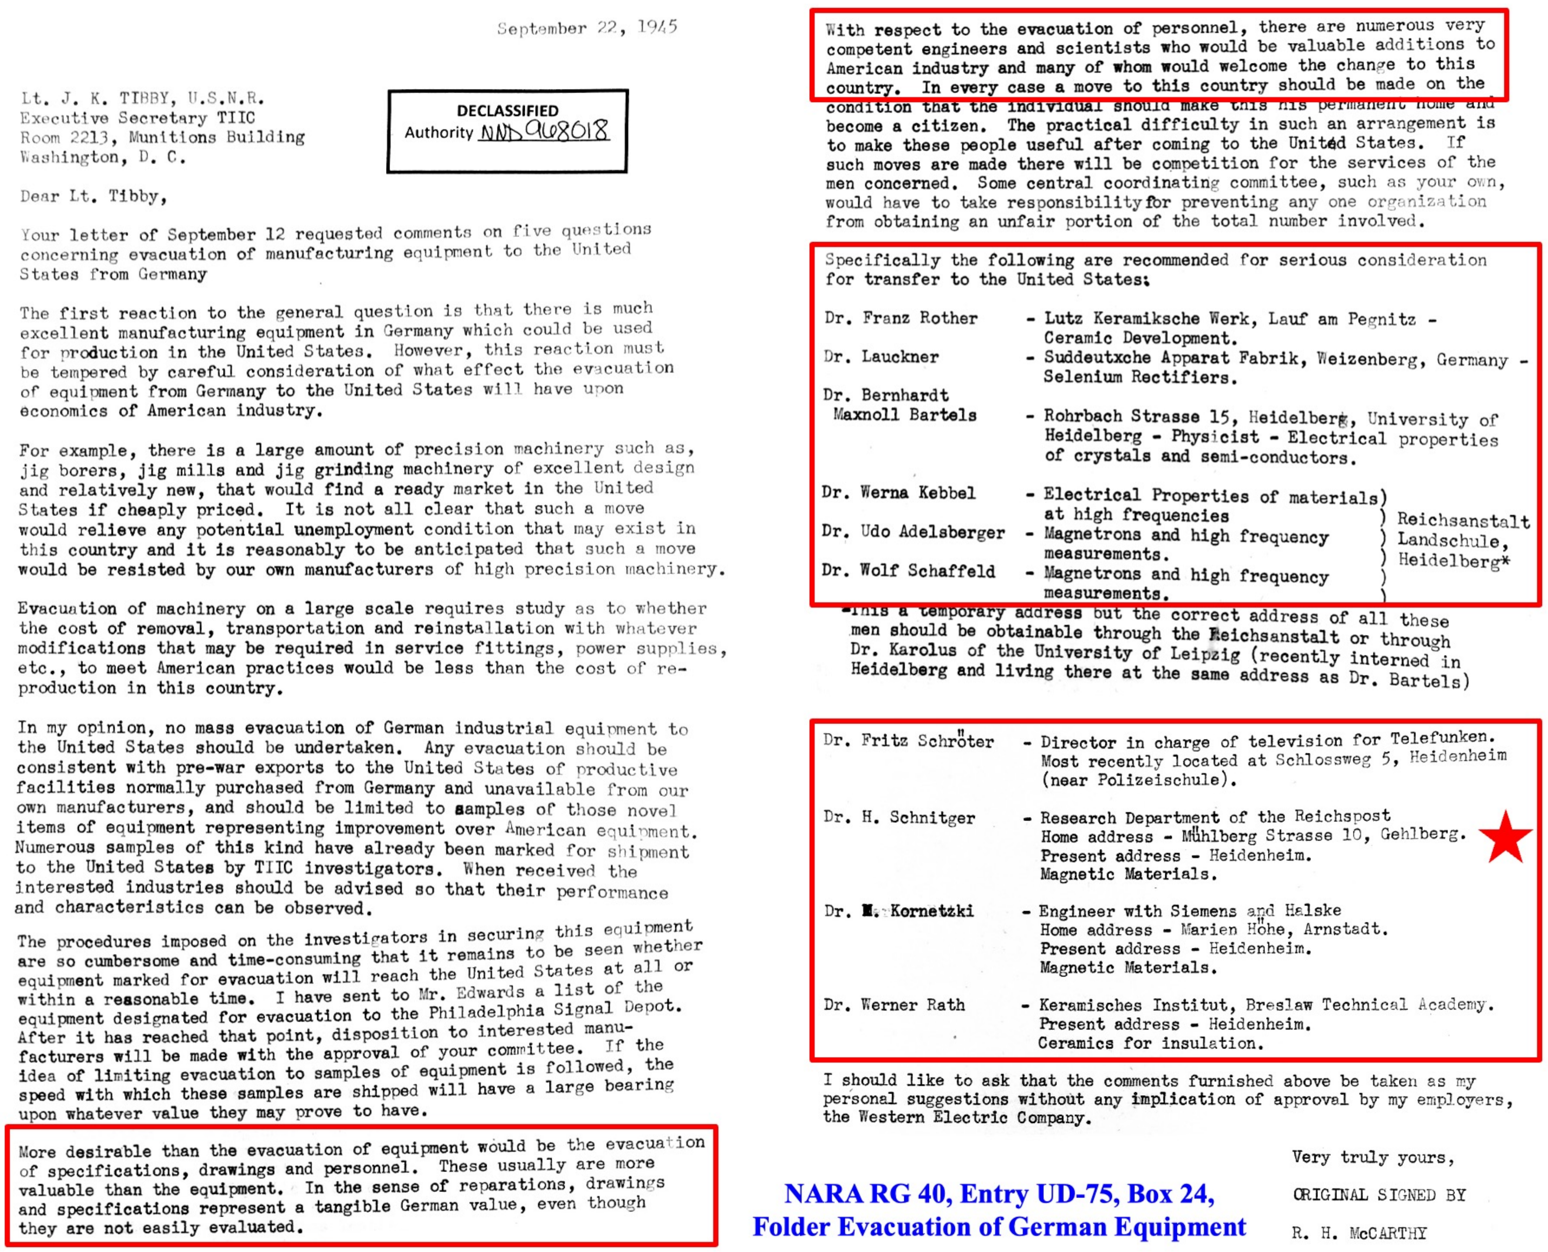
By T. R. KENNEDY Jr.

A novel vacuum tube, not much larger than an ordinary radio receiving bulb, was made public here yesterday. It is expected to do as much for the future of very-high-frequency nation-wide communication as the deForest "audion" did for the broadcast and world-wide telephony and telegraphy pioneers a quarter of a century or more ago.

A product of the Bell Telephone Laboratories, the new device is said to make possible a "wave-guide" network of coast-to-coast proportions over which 10,000 telephone conversations may go simultaneously, or all the television programs needed for all the video stations likely to be operating in this country in years to come.

Figure 6.210: Herbert Schnitger and Dieter Weber in Germany developed traveling wave tube technology that was transferred to AT&T Bell Laboratories after the war [courtesy of Norberto Lahuerta].

Technology Transfer to AT&T Bell Laboratories



September 22, 1945

DECLASSIFIED
Authority NND968018

Lt. J. K. TIBBY, U.S.N.R.
Executive Secretary TIIC
Room 2213, Munitions Building
Washington, D. C.

Dear Lt. Tibby,

Your letter of September 12 requested comments on five questions concerning evacuation of manufacturing equipment to the United States from Germany

The first reaction to the general question is that there is much excellent manufacturing equipment in Germany which could be used for production in the United States. However, this reaction must be tempered by careful consideration of what effect the evacuation of equipment from Germany to the United States will have upon economics of American industry.

For example, there is a large amount of precision machinery such as, jig borers, jig mills and jig grinding machinery of excellent design and relatively new, that would find a ready market in the United States if cheaply priced. It is not all clear that such a move would relieve any potential unemployment condition that may exist in this country and it is reasonably to be anticipated that such a move would be resisted by our own manufacturers of high precision machinery.

Evacuation of machinery on a large scale requires study as to whether the cost of removal, transportation and reinstallation with whatever modifications that may be required in service fittings, power supplies, etc., to meet American practices would be less than the cost of reproduction in this country.

In my opinion, no mass evacuation of German industrial equipment to the United States should be undertaken. Any evacuation should be consistent with pre-war exports to the United States of productive facilities normally purchased from Germany and unavailable from our own manufacturers, and should be limited to samples of those novel items of equipment representing improvement over American equipment. Numerous samples of this kind have already been marked for shipment to the United States by TIIC investigators. When received the interested industries should be advised so that their performance and characteristics can be observed.

The procedures imposed on the investigators in securing this equipment are so cumbersome and time-consuming that it remains to be seen whether equipment marked for evacuation will reach the United States at all or within a reasonable time. I have sent to Mr. Edwards a list of the equipment designated for evacuation to the Philadelphia Signal Depot. After it has reached that point, disposition to interested manufacturers will be made with the approval of your committee. If the idea of limiting evacuation to samples of equipment is followed, the speed with which these samples are shipped will have a large bearing upon whatever value they may prove to have.

More desirable than the evacuation of equipment would be the evacuation of specifications, drawings and personnel. These usually are more valuable than the equipment. In the sense of reparations, drawings and specifications represent a tangible German value, even though they are not easily evaluated.

With respect to the evacuation of personnel, there are numerous very competent engineers and scientists who would be valuable additions to American industry and many of whom would welcome the change to this country. In every case a move to this country should be made on the condition that the individual should make this his permanent home and become a citizen. The practical difficulty in such an arrangement is to make these people useful after coming to the United States. If such moves are made there will be competition for the services of the men concerned. Some central coordinating committee, such as your own, would have to take responsibility for preventing any one organization from obtaining an unfair portion of the total number involved.

Specifically the following are recommended for serious consideration for transfer to the United States:

Dr. Franz Rother	- Lutz Keramiksche Werk, Lauf am Pegnitz - Ceramic Development.
Dr. Lauckner	- Suddeutxche Apparat Fabrik, Weizenberg, Germany - Selenium Rectifiers.
Dr. Bernhardt Maxnoll Bartels	- Rohrbach Strasse 15, Heidelberg, University of Heidelberg - Physicist - Electrical properties of crystals and semi-conductors.
Dr. Werna Kebbel	- Electrical Properties of materials at high frequencies) Reichsanstalt Landschule, Heidelberg*
Dr. Udo Adelsberger	- Magnetrons and high frequency measurements.) Reichsanstalt Landschule, Heidelberg*
Dr. Wolf Schaffeld	- Magnetrons and high frequency measurements.) Reichsanstalt Landschule, Heidelberg*

*This a temporary address but the correct address of all these men should be obtainable through the Reichsanstalt or through Dr. Karolus of the University of Leipzig (recently interned in Heidelberg and living there at the same address as Dr. Bartels)

Dr. Fritz Schröter	- Director in charge of television for Telefunken. Most recently located at Schlossweg 5, Heidenheim (near Polizeischule).
Dr. H. Schnitger	- Research Department of the Reichspost Home address - Mühlberg Strasse 10, Gehlberg. ★ Present address - Heidenheim. Magnetic Materials.
Dr. M. Kornetzki	- Engineer with Siemens and Halske Home address - Marien Höhe, Arnstadt. Present address - Heidenheim. Magnetic Materials.
Dr. Werner Rath	- Keramisches Institut, Breslaw Technical Academy. Present address - Heidenheim. Ceramics for insulation.

I should like to ask that the comments furnished above be taken as my personal suggestions without any implication of approval by my employers, the Western Electric Company.

Very truly yours,

ORIGINAL SIGNED BY

R. H. McCARTHY

UNITED STATES PATENT OFFICE

2,501,876

RADIO SCANNING DEVICE

Reinhold Rüdenberg, Belmont, Mass.

Original application August 14, 1943, Serial No. 498,716. Divided and this application November 19, 1945, Serial No. 629,561

6 Claims. (Cl. 343—100)

1

This is a division of my co-pending application Serial Number 498,716, filed August 14, 1943, now abandoned.

The invention of the parent application is concerned with new methods of and apparatus for reproducing certain distinguishing qualities of distant objects, especially on or near the surface of the earth, on or near the surface of the water and also in the air.

A principal object of the invention disclosed in the said application is a new method of, and new apparatus for, producing a likeness or an image of a distant object; method and apparatus which are operable and effective even under adverse weather conditions—clouds, fog or rain for instance—or insufficient illumination, during the night, or owing to excessive illumination caused by conflagration or the like. More specifically it is an object of the said invention to reproduce as a visible image or representation of an object the electric pattern which corresponds to the contrasts in the electric and magnetic properties of the object.

For attaining to this end, I make use of the phenomenon that an object, such as the surface of the earth, when irradiated by means of electric waves reflects such incident electric waves due to its electric conductivity, magnetic permeability and dielectric constant, if these qualities are different from those of the air. Adjacent parts on the surface, as for example water, soil, rock, or structures of wood, brick, concrete, or metal, have different reflection coefficients. The electric wave reflection is slight at soil, strong at water surfaces, stronger at metallic bodies owing to their high electric conductivity, and particularly strong at iron structures owing to their high magnetic permeability. The reflected electric waves thus form a pattern similar to that of ordinary light. In contrast therewith however, even concealed structures such as steel structures embedded within the ground, a medium of low conductivity, or even on or below the surface of water, manifest themselves in this electric pattern. The present invention makes use of this phenomenon for producing an image of an object by transforming its electric pattern into a visible picture.

It is an object of the present invention to activate this pattern for thus enabling the observer to receive by means and methods disclosed in my aforesaid copending application at an observation or receiving station signals corresponding to this pattern and to transform these signals into a visible image of the object.

For this purpose, in accordance with the invention, the apparatus for activating or producing a radiant image of the electric pattern of a distant object, corresponding to the contrasts in the electric and magnetic properties thereof, includes an oscillator for producing electric waves, a directional electric wave converter connected thereto, and a scanner adapted to control by means of electric rhythms said converter so as to scan the pattern by means of said electric waves.

2

The term "electric wave converter," as used herein, is to comprise generally an electromagnetic device, such as an antenna, a dipole, a dipole array, or any other type of conductor or guide, or system of conductors or guides, linearly, areally, or spatially extended, which forms the source or the sink of the electric waves, or alternatingly both. This electric wave converter thus converts conductor-bound, -conducted or conductor-guided-, electric energy into free radiating energy or, vice-versa, receivers or collects free radiating energy and converts it into conductor-bound energy, or alternatingly both.

The devices of the invention may be employed for producing an image of the electric pattern of the distant object by focussing and irradiating the distant object with the waves produced in accordance with this invention. The signals emanating from the object and produced through this irradiation in accordance with the contrasts in space of the electric and magnetic properties of said object may then be received and converted into a scanned visible image of the pattern preferably by means of methods and apparatus disclosed in my aforesaid co-pending application Serial No. 498,716, filed on August 14, 1943.

A further object of the invention is the arrangement of a scanning device which includes a scanner for producing rhythmical scanning oscillations and a modulator coupled thereto and controlled thereby for displacing the phase of the wave oscillations within the elements of the electric wave converter and distributing over the various of said elements the phase modulating reaction in proportion to the respective positions of said elements within said electric wave converter and controlled in its intensity in accordance with the curve shape of the scanning oscillations and in the rhythm thereof.

Another object of the invention is the arrangement of a scanner which comprises a generator for rhythmic sweep oscillations for oscillating in the rhythm of the sweep oscillations a beam of electric waves converted by said converter and sweeping said beam across the distant object. The modulator is adapted to be excited from the conductor-bound energy of the waves converted in the wave converter and has control elements coupled to the generator for sweep oscillations, reactive elements and output elements, for phase modulating the oscillations within the wave converting elements by means of said reactive elements and controlling the phase modulating reaction in its intensity according to the

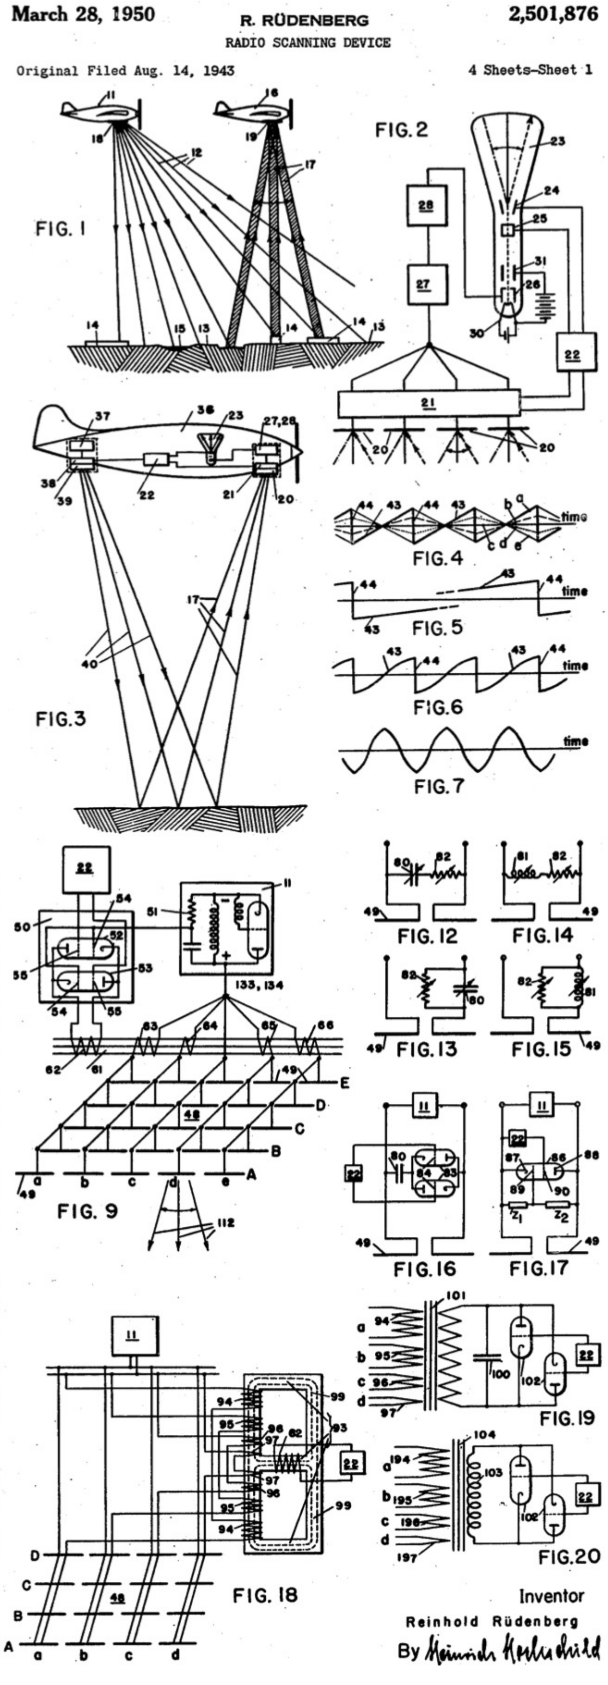

Figure 6.212: Reinhold Rüdenberg (1883–1961) developed phased-array radar systems.

In 1935, information on German radar development and testing reached the United Kingdom. In response, Robert Watson-Watt (Scottish, 1892–1973) began developing a British radar system. That program resulted in the Chain Home radar system. Chain Home was much more primitive than the German radar systems that had inspired it. Whereas the German radars had dishes that could be pointed in any direction or easily moved to other locations, Chain Home was just a series of simple vertical radio towers built at fixed locations on the U.K. coast; it could not be rotated or relocated, and it only detected aircraft over the sea, not over land.

Moreover, Chain Home used a wavelength of around 12 meters (frequency of 25 MHz), while Freya used a much shorter wavelength of around 2.4 meters (frequency of 125 MHz), and Würzburg-Riese had an even shorter wavelength of 0.54 meter (frequency of 560 MHz). That difference in wavelengths meant that the Chain Home antennas had to be 5–22 times larger than the German radar antennas, and Chain Home could only detect objects that were ∼6 meters or larger, whereas Würzburg-Riese could detect objects as small as ∼0.27 meter.

Despite its simplicity, Chain Home was used effectively in defending the United Kingdom from German air raids. In conventional histories written by English-speaking historians after the war, Watson-Watt was erroneously proclaimed to be the "inventor" of radar, and the supposed British lead in radar over Germany was cited as one of the reasons for the Allied victory in the war.

Moreover, in 1940, John Randall (English, 1905–1984) and Harry Boot (English, 1917–1983) began building simple cavity magnetrons for improved British radar systems. Their work was almost certainly based directly on the cavity magnetrons that had been invented, built, and patented internationally five years earlier by Hans Erich Hollmann (which in turn were based on the even earlier work by Gerdien, Habann, and Žáček). Famously, the British cavity magnetron designs were transferred to the United States by Henry Tizard's British Technical and Scientific Mission in September 1940. Most historians in the English-speaking world laud the work of Randall and Boot and the subsequent U.S. work that it inspired, while unfortunately ignoring the documented history of how that radar technology was actually invented years earlier in the German-speaking world and disseminated via international patents and publications.

Even Reginald V. Jones (English, 1911–1997), one of the top physicists in U.K. military science programs during World War II, tried later in life to correct the myths that had accumulated about the alleged British origins and alleged British superiority for radar technologies. In his foreword to David Prichard's *The Radar War*, Jones wrote [Pritchard 1989, pp. 7–8]:

> We in Britain are inclined to think that radar originated in Britain in 1935, stimulated by the threat from the Luftwaffe that was to materialize so dramatically in 1940. It may therefore come as a surprise to find not only that the basic idea of detecting objects by reflected radio waves had been conceived before the First World War, but also that it has been experimentally demonstrated as early as 1904 by a German engineer, Christian Hülsmeyer.
>
> In this book David Pritchard gives much the fullest account of Hülsmeyer's work that is available in the English language, and he then goes on to tell how radar was taken up by the German Armed Services in the years leading up to, and during, World War II. [...]
>
> As the story unfolds, with its many manifestations of German competence in the radio field, we in Britain can be increasingly thankful that the intensity of the Luftwaffe threat

> in the years leading up to 1939 brought our serving officers and scientists together at all levels into a close working relationship: it was this, more than any other factor, which resulted in our lead in the operational use of radar even though in some respects the German equipment was technically better.

The radar historian Pritchard described in detail how WWII British radar experts learned that German radar systems were much more advanced than British systems [Pritchard 1989, pp. 97–99]:

> It is no exaggeration to say that after examining the *Würzburg* [captured in the 28 February 1942 Bruneval raid] the British received quite a surprise.
>
> Even on the way home in the boat D. H. Priest, a radar specialist from TRE [Telecommunications Research Establishment] who had gone on the mission, had had time to examine it, and during an exchange of opinions with Cox came to the conclusion that the Germans had been making it for a long time, possibly even ten years.
>
> Cox, who had been in radio all his life, thought the *Würzburg* was a 'beautiful job', and was particularly impressed by the way it made use of unit construction for easy fault-finding and quick replacement, a view also shared by Jones. [...]
>
> The equipment had therefore to be made so well, and so easily replaceable if any part broke down, that the system could be operated by relatively unskilled personnel.
>
> The superiority of the engineering standard was indeed much higher than the British systems, and to ensure that no lack of morale appeared in engineering and (later) public circles, a story was disseminated (and still believed by some today) that German radar was much inferior to the British. That this was wildly inaccurate is however attested by those who at the time were in possession of the facts, as Jones points out:
>
> > ...the stability of every German radar station was better than that of the best instruments we had available to check them. In fact, Martin Ryle, afterwards to win a Nobel Prize for Radioastronomy, was one of our observers, and he told me that ever afterwards if he wanted to know whether a radar transmission was British or German, all he had to do was to check its stability.
>
> To achieve and maintain these standards, and even to improve upon them in the face of political and military dissension, and in spite of severe disruption of the production lines from Allied bombing, to say nothing of the strain of a war economy, must remain for all time a tribute to the skill and determination of all those involved in the German radar programme.

Because the wartime German radar systems had such advanced capabilities compared to British and American radar systems of the time, after the war they were transferred to other countries to be used and copied. Jones gave several examples [Jones 1978, p. 230]:

> If the German night interception procedure seemed unduly elaborate, the precision of the Giant Würzburg was not entirely wasted on the war: in 1945 specimens were brought to Britain and America and converted to radio telescopes for radioastronomy. Another specimen that remained on site in Holland was used by Dr. van de Hulst to discover the radiation coming in from the hydrogen atoms in the spiral arms of our galaxy on a wavelength of about 21 centimetres.

6.8.2 Radar Countermeasures

Scientists in wartime Germany pioneered radar countermeasures or stealth technologies. They created and tested a variety of radar-absorbing coatings, and gave the best ones names such as Eisenspane and Moltopren.[25] Germany successfully used those radar countermeasures on submarines, and it was developing and testing stealth aircraft as well; see pp. 1768, 1773–1774.[26]

Documentation, materials, and scientists from those wartime programs on radar countermeasures were acquired by Allied countries after the war and became the basis for modern stealth technologies. Some examples are below, but much more historical research on this topic should be conducted and published in the future.

Former Bell Laboratories scientist T. M. Odarenko gave an overview of some of the German programs in FIAT 61, *Radar Camouflage Radiation Absorption Materials*, pp. 1, 12–13:

> The problem of radar camouflage and radiation absorbers is not new to the radar workers in the U.S. The Radiation Laboratories and the War Committee on Dielectrics, among others, were concerned with it. [...] Because of the urgency of other problems, the work in U.S.A., however, did not progress very far. The Germans, on the other side, who placed high hopes in their submarine warfare, and whose submarines suffered severely from high losses due to the radar detection methods of the Allies, invested a great deal of efforts, and of scientific and of technological talents, into the anti-radar methods and devices. The results of their work prove to be of considerable interest to the allied intelligence organizations. [...]
>
> By the end of the European war, the Germans investigated the theoretical approach to the radiation camouflage quite exhaustively. Much practical data was accumulated by the Germans on the tuned and wide-band lossy “impedance-matching” absorbers. In addition, materials were produced successfully with permeability equal to dielectric constant and with reasonably high losses. As the side results of their work on the semiconductors, means were established of introducing high electrical losses into materials.
>
> As the result of the fundamental study of dielectric materials and various ferrites and oxides, new materials were obtained, the electromagnetic constants of which could be controlled by such factors as temperature, magnetic field, etc.
>
> The problem of an ideal radiation absorption material has not been solved in Germany. The Germans, however, went far enough to indicate that further researches on such materials are well worth while. Their failures with certain materials, and their successes with others, might assist this further work considerably if their results with complete reports and data are made promptly available to the proper research organizations in this country and in Great Britain.

[26] Horten and Selliger 2012; Jorgensen 2009; Myhra 1998b; Shepelev and Ottens 2015.

> The importance of this work lies in the fact that the materials thus developed would be of interest not only in the strictly military field, where radars have proven of such value, but in the variety of other applications, such as selective shielding, static dissipators, tuned networks, etc.

BIOS 871, *Work of Professor Hüttig on Ferromagnetic Substances for Use in Radar Camouflage*, pp. 4–5, also described some of the wartime programs:

> Hüttig, who is essentially a physical chemist, and specialises in the properties of the solid state, worked on Schornsteinfeger in collaboration with a team including Professor Kafla, physicist, and Professor Flegler, who made the electro-magnetic absorption measurements. Their objective, as has already been noted, was the production of a ferromagnetic material with permeability and dielectric constant equal and high, and if possible lossy. The material first studied and developed to the production state, was gamma iron oxide, and this can be produced on a manufacturing scale with μ equal to *epsilon* equal to 6, with no loss. This material, known as W.61, was manufactured at the DEGUSSA works in Raudnitz-on-Elbe, and was rolled into Buna at Uhrineves, near Prague, giving a product containing 10% Buna and 90% W.61.
>
> Owing to the instability of gamma iron oxide and to the fact that the material is not lossy, attention was then turned to the development of ferrites. [...] A large number was prepared[...]
>
> Hüttig said that the most promising material was probably manganese ferrite from the point of view of giving the properties required, although for consistency in production, magnesium ferrite would be preferable. The best samples of manganese ferrites that his team had prepared had a permeability of 12 and a dielectric constant of 18 with magnetic and dielectric losses both equal to 0.35, the measurements being made at a wave length of 173 cm. [...]
>
> Hüttig was of the opinion that the system ferrous oxide–vanadium oxide was worth study, as the material had a very high ferromagnetism and formed solid solutions with metallic iron.

British Aerospace/BAE engineer Ronald Evans explicitly stated how dependent postwar Allied programs to develop stealth aircraft were on wartime German creations [Evans 2015, p. xv]:

> From 1978 until 2005, I was employed by British Aerospace and, after the merger with Marconi, by BAE Systems at their military aircraft site at Warton Aerodrome in Lancashire[...]
>
> I began work at Warton as a senior aerodynamicist in the Performance & Propulsion Group. [...] In 1980 I was tasked with running a radar stealth research programme. Capitalising on German development of radar-absorbing materials (RAM) during the Second World War, the UK became a world leader in reducing the radar signatures of its military aircraft during the 1950s and 1960s. [...] In 1962 there was a large exchange of information on the subject of radar stealth between the UK and US governments.

6.8.3 Microwave Heating

According to conventional histories, in October 1945, Percy Spencer (1894–1970), an American with only a high school education working as a business manager at Raytheon, suddenly invented, built, demonstrated, and perfected microwave ovens.

In fact, it was large numbers of highly educated German-speaking scientists at Siemens, Telefunken, and other German companies who worked diligently over the course of a decade to:

1. Invent microwave heating in the 1930s.
2. Perfect and apply it to a wide variety of applications (food preparation, delousing of clothing, glue drying, etc.) during the war.
3. Transfer the technology under duress after the war to Allied countries, which then publicly claimed it as their own postwar invention.

BIOS 866, *High Frequency Heating*, is a key piece of evidence documenting that history (Fig. 6.215):

> [p. 1:] This report contains a survey of the activities in the field of high frequency heating of the German industry and it has been compiled from information gained at 18 targets in the British, U.S. and French zones. It deals chiefly with work at Radio Frequencies and is not concerned with the use of rotating machines.
>
> Most of the activity has been confined to the large electrical firms particularly SIEMENS SCHUKERT, A.E.G. and TELEFUNKEN, and mainly in the Berlin sections of these companies.
>
> It would appear that in 1939 the Germans were fully aware of the industrial possibilities of high frequency heating and were reasonably far advanced in the techniques involved. During the war practically all the effort was devoted to essential war work and development appears to have been impeded to a considerable extent by government restrictions on the use of valves.
>
> Practically no equipment was seen. It was reputed to have been destroyed by bombing or removed by the Russians. Sets up to 20 kW or thereabouts had been made in some quantities for surface hardening and larger sets up to 200 kW for this field had been planned.
>
> Dielectric heating had been experimented with in many fields such as wood gluing; drying of timber, cigarettes etc; plastics heating; lice-killing and food processing. Only wood gluing for aircraft and lice killing in soldiers' uniforms had been applied on any scale.
>
> [p. 16:] (ix) SIEMENS-SCHUKERT WERKE BERLIN-SIEMENSSTADT [...]
>
> Induction Heating had been applied to surface hardening of gears and other articles at frequency of 100-200 kc/s using powers up to 200 kW.
>
> Dielectric Heating had been tried with wood drying, wood gluing, rubber vulcanisation, tobacco drying, plastics heating, milk sterilisation, wheat drying, meat cooking and

> drying, and killing of lice. Only wood gluing and lice killing had been put into practical application.
>
> Personnel Interviewed.
>
> > Mr. BENKERT, director and works manager.
> > Dr. MAIER, assistant to Mr. BENKERT.
> > Mr. ASCHMANN, in charge of industrial applications.
> > Dr. SCHNECKE, in charge of equipment design.
> > Dr. TSCHERMAK, in charge of dielectric heating.
> > Mr. KEUTNER, dielectric heating.
>
> [p. 18:] (a) Wood gluing: This was done chiefly for the aircraft industry and when the war ended 12 sets at 6 Mc and 20 kW had been installed for making plywood and general gluing of aircraft parts. [...]
>
> [p. 19:] (b) Killing lice in garments: The sets operated at 25 Mc/s with a power of 30–40 kW and 3 stationary and 1 mobile equipments had been supplied to the WEHRMACHT for treating uniforms. The uniforms were sprayed with water then carried through a condenser field on a leather conveyor at the rate of 400 Kg of clothing per hour. It was claimed that lice, eggs and typhoid bacteria were all killed.
>
> [pp. 22–23:] (xii) TELEFUNKEN.
> BERLIN-SCHÖNEBERG, MAXSTRASSE 10. [...]
>
> Dr. FRANZ stated that the limited resources available for H.F. Heating were being devoted in the first place to heating of foods with a view to making the most of the supplies available. After food heating work would be done on plastics.
>
> In conjunction with SAROTTI, a subsidiary of NESTLES experiments were being done on pre heating grain or flour. It was found that Rye flour heated in this way to a temperature of 150^{o}C had improved quality and it could be used in place of wheat flour for making soups. Cereals treated similarly by H.F. heating could be kept easily and were in a pre-cooked state requiring little cooking when they were to be used.
>
> The experiments were being done on a small scale with a 1 kW oscillator on a frequency between 15 and 30 Mc/s. About 0.5W per gm were required.
>
> Dr. FRANZ considered that there was quite a future for this activity.
>
> Demonstration experiments on cooking potatoes were mentioned. It had been found with H.F. heating that the water need not boil as long as in ordinary potato cooking. Thermocouple measurements had shown that with the H.F. heating the potato temperature was in advance of the water temperature.
>
> These food experiments were being done in co-operation with the "Food Institute".

As the above document mentioned, German-speaking scientists also invented and perfected induction heating, which is now used in the most modern type of stovetops.

Microwave ovens were developed by 1939 by scientists at:

- **AEG**
- **Siemens Schuckert**
- **Telefunken**
- **Etc.**

Demonstrated applications:

- **Food preparation**
- **Wood glue drying**
- **Drying of timber**
- **Killing lice in clothing**
- **Etc.**

HIGH FREQUENCY HEATING.

1. SUMMARY.

This report contains a survey of the activities in the field of high frequency heating of the German industry and it has been compiled from information gained at 18 targets in the British, U.S. and French Zones. It deals chiefly with work at Radio Frequencies and is not concerned with the use of rotating machines.

Most of the activity has been confined to the large electrical firms particularly SIEMENS SCHUKERT, A.E.G. and TELEFUNKEN, and mainly in the Berlin sections of these companies.

It would appear that in 1939 the Germans were fully aware of the industrial possibilities of high frequency heating and were reasonably far advanced in the techniques involved. During the war practically all the effort was devoted to essential war work and development appears to have been impeded to a considerable extent by government restrictions on the use of valves.

Practically no equipment was seen. It was reputed to have been destroyed by bombing or removed by the Russians. Sets up to 20 kW or there abouts had been made in some quantities for surface hardening and larger sets up to 200 kW for this field had been planned.

Dielectric heating had been experimented with in many fields such as wood gluing; drying of timber, cigarettes etc; plastics heating; lice-killing and food processing. Only wood gluing for aircraft and lice killing in soldiers' uniforms had been applied on any scale.

In the report below the activities are reviewed firstly under subject headings and secondly under target headings.

2. SUBJECTS/

Figure 6.215: Microwave ovens were developed no later than 1939 by scientists at AEG, Siemens Schuckert, Telefunken, and other laboratories. They were demonstrated to be effective for applications including food preparation, wood glue drying, drying of timber, killing lice in clothing, etc. The technology was transferred to Allied countries after the war [BIOS 866].

6.8.4 Sonar

German-speaking scientists invented underwater acoustic ranging and imaging technology in the early twentieth century and developed highly sophisticated and specialized systems by the 1930s and early 1940s.[27] This technology is now best known by the WWII-era American name sonar (originally an acronym derived from SOund NAvigation Ranging). In many early Allied documents, this technology was also called ASDIC (after the Anti-Submarine Division).

Alexander Behm (German, 1880–1952) invented and demonstrated sonar in 1912. Leo Löwenstein (German, 1879–1956) was another early German sonar pioneer. Independent work on sonar began in other countries within that same decade, especially in response to Germany's use of submarine warfare in World War I.

German-speaking scientists steadily improved sonar technology from World War I through World War II. By World War II, at least four companies had large programs developing and manufacturing sonar systems:

1. Atlas Werke based in Bremen.
2. Electroacustic Kommanditgesellschaft (ELAC) based in Kiel.
3. GEMA (Gesellschaft für Elektroakustische und Mechanische Apparate) based in Berlin.
4. AEG (Allgemeine Elektrizitäts-Gesellschaft) based in Berlin.

Improvements to German sonar technologies continued until the end of World War II, at which point they were transferred to Allied countries. For example, NavTecMisEu 530-45, *Sonar in the German Navy*, p. 2, stated:

> The GHG is the German counterpart of the multi-spot equipments which were abandoned in the U.S. before the war. The Germans, however, carried the principle to a much higher degree of development and appear to have attained excellent results. The GHG ordinarily permits detection at much longer range than supersonic [ultrasonic] listening or echo ranging gear.
>
> The other important class of German equipment is the S Anlage for echo ranging and supersonic listening. This apparatus was well designed, with emphasis on simplicity and reliability.

German companies also applied sonar methods to the air to create sonic altimeters for aircraft.[28]

After the war, many German sonar experts continued their work in Allied countries.

Robert Adler (Austrian, 1913–2007) invented ultrasonic remote control systems; see p. 1012.

Accepted, 15th July, 1915

COMPLETE SPECIFICATION.

Improvements in or relating to a Method of and Apparatus for Measuring Distances under Water by means of Reflected Sound Waves.

I, ALEXANDER BEHM, of Hardenbergstrasse 31, Kiel, German Empire, Physicist, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

It has been repeatedly suggested to measure the depth at sea and distances under water, by determining the time between the sending off of an acoustic signal and the arrival of the echo. In this method the direction is determined by turning a funnel situated at the transmitter or at the receiver, in which case the ear of the observer has to decide when the intensity of sound of the echo is the greatest. As the velocity of sound under water is about 1435 meters per second, this method could be utilised only in very deep water or for large distances, whilst in the case of small distances it failed completely. Moreover, in this and similar methods, the measurements are uncertain as the returning sound is received by the ear directly or indirectly by means of a microphone.

These disadvantages are obviated according to this invention,

1) By using a sonometer *viz.* an instrument for measuring the strength of sound waves by observation of the deflections of a body caused to vibrate by the sound waves which does away with the source of error lying in observation by the ear, and

2) By measuring the strength of the echo, which decreases with the distance, instead of taking as a basis the time elapsing between the emission and return of the signal. If the intensity of sound of the transmitter remains constant, the receiver can be provided with a graduation on which the distance or the depth of the sea can be read directly. The intensity of the transmitter could however also be increased or reduced until a given intensity of echo, determined beforehand, is obtained. The intensity of the source of sound, which can be measured by means of the sonometer, then gives the measure of the depth or the distance.

1.2 Sources of Information.

The material contained in this report was gathered in the course of three field trips totalling 40 days in Germany. Equipment was inspected on board ships afloat and on the building ways, in warehouses, test laboratories, and factories of the leading manufacturers. Information was gathered from various personnel as well as from documents. The more important personnel interrogated include:

Konteradmiral Rhein of the CPVA (Chemische Physikalische Versuchs Anstalt)
Dr. Ing. Buchmann of the CPVA.

Dr. Ing. Bluschke of the CPVA.
Fr. Kapt. Meckel of the OKM (Oberkommando der Kriegsmarine).
Kapt. Von Linden of the SVK (Sperrversuchskommando).
Kapt. Hagemann of the SVK.
Oblt. Dr. Matusche of the Luftwaffe.
Dr. Ing. Karl Kupfmuller of the WFM (Wissenschaftlicher Fuehrungsstab der Kriegsmarine.)
Dr. Rudolf Kuhnhold of the NVK (Nachrichtenmittelsversuchskommando).
Dr. Phil. Friedrich Howey of the NVK.
Dr. Schmidt of the NVK.
Dr. Hans-Ulrich Meyer of the NVK.
Dipl. Ing. Hummel of the NVK.
Dr. Kurte Kalle of the Deutscheseewart.
Prof. Dr. Ervin Meyer of the Berlin Technische Hochschule.
Dr. Hermann Oberst of the Berlin Technische Hochschule.
Herr Nickelsen of Elecktroacustic.
Dr. Ing. Heinrich Hecht of Electroacustic.
Dr. Ing. F. A. Fischer of Electroacustic.
Dr. Ing. Fahrentholz of Electroacustic.
Dr. Ing. Karl Hecht of Electroacustic.
Dr. Ing. W. Kunze of Atlas Werke.
Dr. Ing. Kietz of Atlas Werke.
Dr. Ing. Grandiot of Atlas Werke.
Dr. Ing. Maass of Atlas Werke.
Dr. Ing. Theide of Atlas Werke.
Dr. Ing. Jenkel of Atlas Werke.
Dipl. Ing. Isola of Atlas Werke.

1.3 Development and Manufacture.

The majority of the German underwater sound equipment was developed and manufactured by the firms of Atlas Werke in Bremen and Electroacustic Kommanditgesellschaft (Elac) in Kiel. Each of these firms had dispersal plants in other areas. Elac has been in business since 1926 and Atlas even longer. The two firms operated under very keen competition before the war and furnished substantially equal quantities of similar equipment. At the start of the war the firm Gema (Gesellschaft fur elektroakustiche und mecanische Apparate mbH.) and

Figure 6.220: Atlas Werke, ELAC, GEMA, and AEG developed highly sophisticated and specialized sonar systems [NavTecMisEu 530-45].

6.8.5 Sonar Countermeasures

German-speaking scientists led by Erwin Meyer (German, 1899–1972) invented, perfected, and installed highly effective sonar-absorbing rubber coatings (code-named Alberich) on submarines such as U-480.[29]

BIOS 526, *Development and Manufacture of Alberich*, pp. 3–4, summarized the history of that program:

> 2. Organisation:
>
> Dr. Kieskalt was head of the section at I.G. Farben concerned with the development of anti-asdic coverings for submarines. The section was directly under the control of N.V.K. with Professor Erwin Meyer of the Technische Hochschule, Berlin, as Scientific Advisor. Professor Meyer was also in touch with the section through Dr. Oberst, a member of his team at the Hochschule.
>
> The scientific and development work was carried out at I.G. Farben at first by Dr. Brennschede, a physical chemist, and later by Drs. Patat and Mehnert. Patat, a physical chemist, was more concerned with the chemistry of the material, while Mehnert, a physicist under the guidance of Meyer was responsible for the designing and testing of the punched material. Dr. Ing. Laüer, who was employed at one time by Meyer, assisted Mehnert with the measurements which were made at Höchst and at Pelzerhaken.
>
> Engineering and workshop requirements were controlled by Ob. Ing. Geiger with Ing. Möller, Rechert, and Wieswar assisting. Geiger was a reserve U-boat Captain who was brought back at Kieskalt's request in April 1940. Rechert dealt with the firm of Sorst & Co., Hanover, who was responsible for the punching of the sheets. Wieswar was at Offenbach supervising the cementing of the sheets and Möller was responsible for the actual covering of the boats in the yards.
>
> The cements were manufactured at Höchst and were developed by Dr. Schaich, assisted by Dr. Koren.
>
> The buna sheet forming the basis of the material was manufactured by three or four specialist firms and sent to I.G. Farben at Offenbach, to be ground to the requisite thickness. Part of the material was then forwarded to Hanover to be punched by Ernst Sorst & Co., who returned it to Frankfurt where at I.G. Farben, Offenbach, the finished two-ply covering was produced and wrapped ready for shipment to the yards. Testing of samples was carried out at I.G. Farben, Höchst.
>
> Shortly before the end of the war plans were being made for the centralisation of the manufacturing processes in a new factory at Einbek, Hanover, to be under the direction of Sörst. A programme involving the covering of 80 boats was planned to take effect from April, 1945. Up to the cessation of hostilities with Germany only 10 boats had been covered, including two experimental models.

---

[29] Ruthven and Bardehle 2009; BIOS 210; BIOS 526; CIOS XXIV-8; NavTecMisEu 352-45.

3. Early attempts by I.G. Farben to solve the problem:

Kieskalt stated that early in 1940 he developed a sound absorbent surface for anti-asdic work which comprised a number of rubber cones filled with a plastic material, such as "Mowilith". Designed for a frequency range of 7–15 kc/s, said to be that of our asdics, the cones were about 100 mm. in height and spaced 50 mm. apart. Trials in the Baltic were carried out in the spring of 1941 with a submarine U-9 coated with the material but it was apparent that this solution was not a practical one.

4. Development of Alberich:

In 1941 Professor Erwin Meyer, in the search for a solution which could be used under operational conditions, introduced the idea of a resonant absorber composed of a two-ply rubber sheet, one ply of which is perforated. The theory underlying the operation of this material has already been discussed with Meyer (v. SRE/I/206) and Kieskalt had nothing further to add to this aspect of the problem.

5. Choice of raw material:

Preliminary experiments on this resonant type of absorber using existing rubber mixes, such as those prepared for the manufacture of linings for chemical engineering plant, enabled more precise requirements to be formulated. Important features, distinct from the dynamical properties of the material, were:-

(a) resistance to oil and sea-water.

(b) non-ageing.

(c) capable of being cemented to self and to the hull of a submarine.

(d) resistance to mechanical wear and abrasion.

6. Manufacture of sheet and cement:

[...]

After the war, scientists, materials, and information related to sonar countermeasures were transferred to Allied countries, guiding further work in this area.

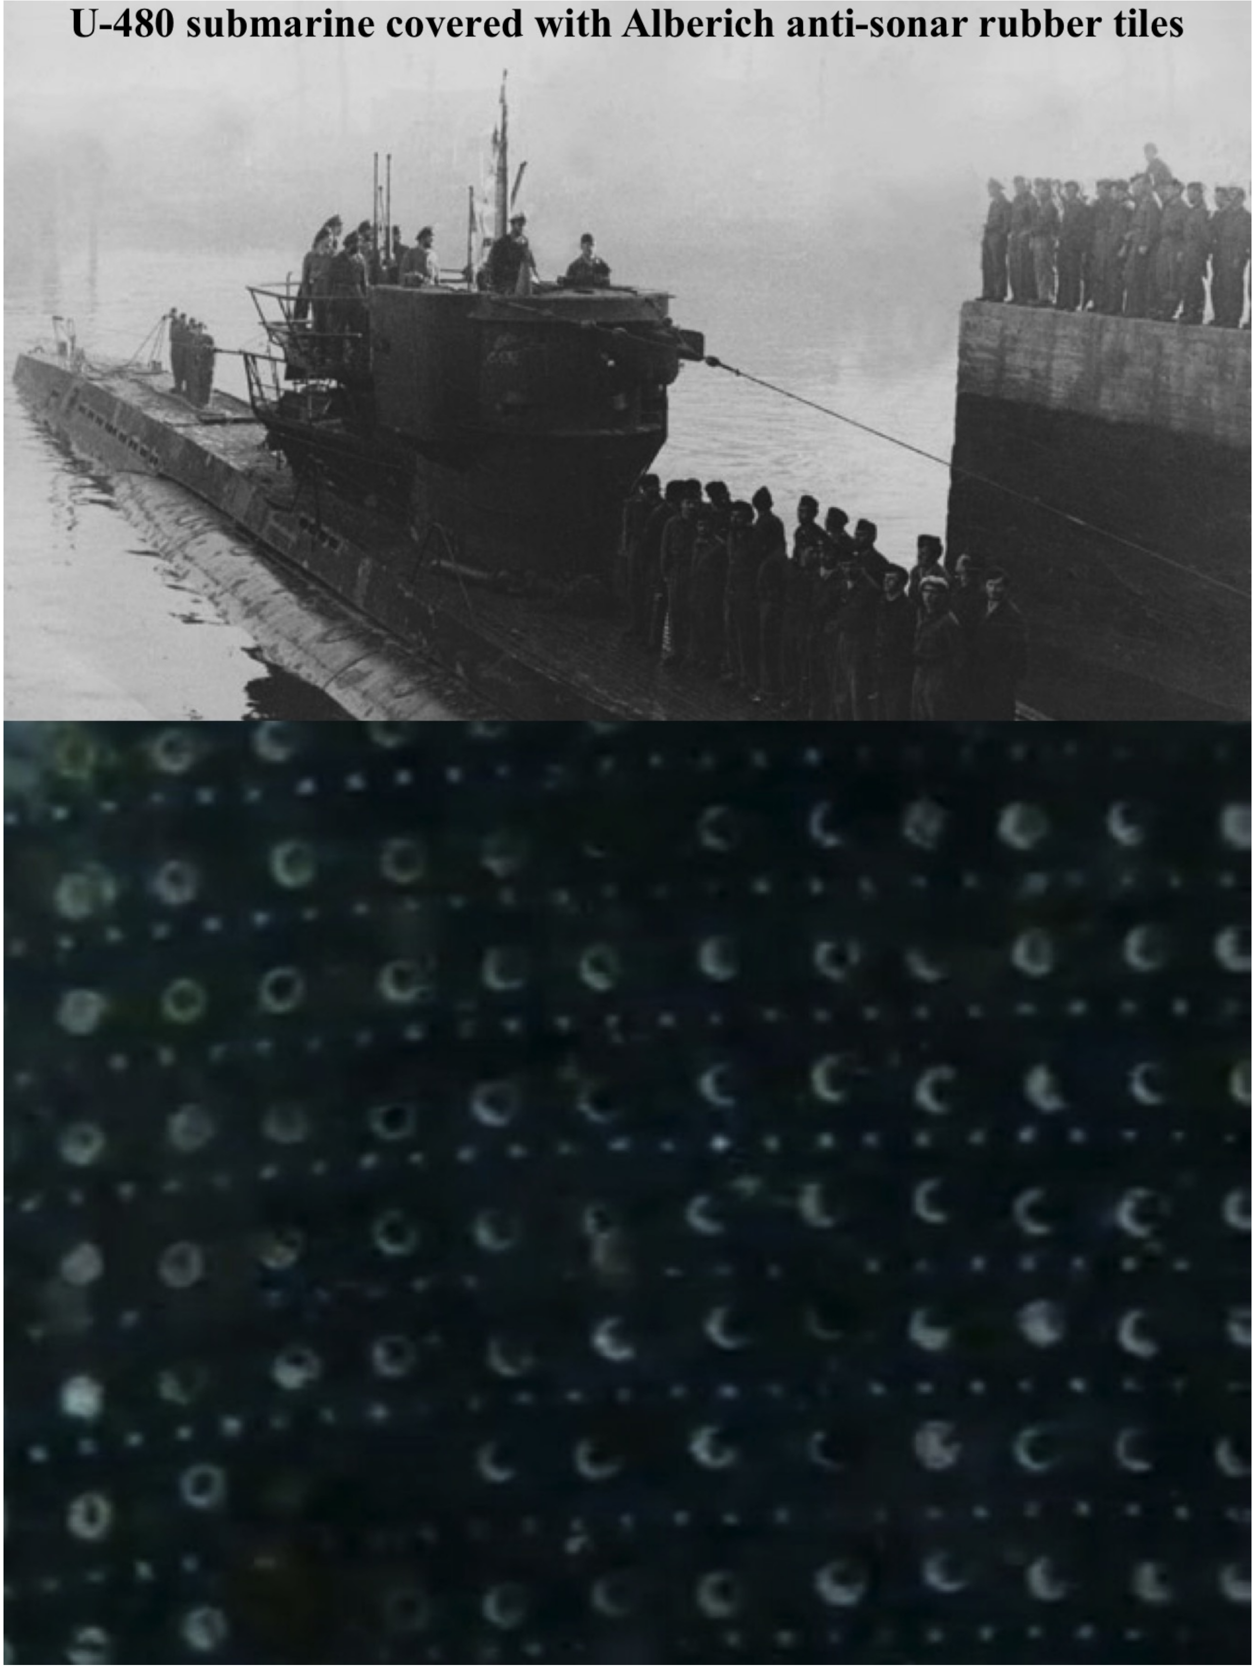

Figure 6.221: U-480 submarine covered with Alberich anti-sonar rubber tiles.

6.8.6 Ultrasound Imaging

During World War II, German-speaking scientists developed and demonstrated ultrasound imaging systems for both industrial and medical applications [Woo 2006; BIOS 609; BIOS 1679]. After the war, those technologies and in many cases the scientists themselves were transferred to Allied countries to optimize and commercialize ultrasound imaging in those countries.

Some of the major creators who developed ultrasound imaging systems included (Fig. 6.222):

- Karl Theodore Dussik (Austrian, 1908–1968) pioneered the use of ultrasound imaging for medical applications, beginning with his first research proposals in 1941, first hardware in 1942, and first experiments with medical imaging around 1945.
- Carl Hellmuth Hertz (German, 1920–1990), the son of Gustav Hertz (p. 893) and great nephew of Heinrich Hertz (p. 854), developed echocardiography, which uses ultrasonic waves and acoustic signal recording and imaging methods to analyze heart function. He obtained the first echocardiogram in 1953 (p. 336). He also developed inkjet printing.
- Theodor Hueter (German, 19??–19??) developed ultrasound imaging systems at Siemens during the war, and at MIT and Raytheon in the United States after the war.
- Paul Kretz (Austrian, 19??–19??) founded Kretztechnik after the war and produced ultrasound imaging systems for both industrial and medical applications.
- Carl Kretz (Austrian, 1932–20??), the nephew of Paul Kretz, joined Kretztechnik and took over the development of improved ultrasound imaging systems.
- Heinrich Netheler (German, 1909–1999) began developing ultrasound imaging systems for medical applications in 1943. After the war, he founded the company that ultimately became known as Eppendorf to continue developing that and other biomedical technologies.
- Reimar Pohlman (German, 1907–1978) at Siemens developed and demonstrated ultrasound imaging systems for industrial applications by 1943. See Fig. 6.223.

During World War II, German-speaking scientists also invented and successfully demonstrated acoustic systems for sonication of materials and for other applications. Those technologies were also transferred to Allied countries after the war.

For more information, see Section C.4.

6.8.7 Acoustic Weapons

Richard Wallauschek (Austrian/Czech, 1912–1962), a physicist from Telefunken, was funded by Albert Speer during the war to create acoustic weapons at a dedicated laboratory in Lofer, Austria. By 1945, he had developed and demonstrated an incapacitating weapon that could create a focused beam of sound waves with 134 dB (1 millibar) of intensity at a distance of 60 meters (Fig. 6.224). His technology was transferred to Allied countries [CIOS XXXII-77] and led to modern systems such as the Long-Range Acoustic Device (LRAD).

For more information, see Section C.4.

6.8.8 Radio and Acoustic Proximity Fuses and Homing Devices

As already covered, one postwar myth of Allied scientific superiority is that the United Kingdom invented radar and Germany lagged behind, even though there is abundant documentation that the opposite was true. A similar example of postwar historical revisionism by English-speaking historians is that Germany failed to develop a proximity fuse whereas the Allies did. (The Allied "VT" or Variable Time radar proximity fuse was deployed in 1944.)

In fact, scientists in Germany and Austria began work on proximity fuses and homing devices in the 1930s. From the 1930s to 1945, they invented a vast assortment of proximity fuses and homing devices. They created sensors based on active acoustic, passive acoustic, active radar, passive radar, electrostatic, infrared, remote television, and other approaches. They created sensors for guided missiles, smart bombs, artillery shells, and torpedoes. Those systems were documented in numerous postwar Allied reports such as:

For example, CIOS XXXII-125, *German Guided Missile Research*, reported (p. 5411):

> A.E.G. have developed an electronic proximity fuse which was said to be in mass production. It consisted of a unipole mounted on the nose of a missile, and tightly coupled to a small CW oscillator. A second oscillator was also incorporated which ran at a

> frequency of 800 c/s less than that of the first. The beat frequency was obtained in a mixer. In the proximity of an aircraft or other large conducting body the frequency of the first oscillator was pulled by the change of aerial impedance and the beat frequency increased. The latter signal was passed through a 1000 c/s filter the output of which operated the fuse.

U.S. Army Air Forces Colonel (later General) Donald Putt noted [Putt 1946b]:

> The Hs-117 [...] was a ground-to-air missile. It was named Schmetterling or butterfly, and was a rocket-propelled, radio-controlled missile to be launched from the ground against bomber formations. It accelerated to a speed of 560 mph, and was steadied in flight by a pendulum device. The take-off rocket burned out and were jettisoned; the main propulsion unit then drove the missile until it was detonated by a proximity fuse. Large-scale production began January, 1945, in an underground factory in Nordhausen. [...]
>
> The Rheintochter [...] was a ground-to-air missile. It was a rocket-propelled anti-aircraft weapon and was controlled in flight by radio. It traveled at a speed of 1100 mph and carried an explosive charge of 330 lb, equipped with a proximity fuse, to a ceiling of 48,000 ft. The starting rocket, attached to the base, was blown off after combustion was completed. Development did not go beyond the test firing stage, but experiments were still being conducted as late as February, 1945.

In November 1945, General Henry Arnold reported (p. 5456):

> At lower right is the X-4, a wire controlled, rocket-propelled gyro-stabilized missile, to be launched from parent plane against bombers. X-4 was almost ready for use. [...] Potency of X-4 (right) was tremendously increased by proximity fuse.

In June 1945, General Carl Spaatz requested the air lift evacuation of Rheintochter missiles with proximity fuses (p. 5664):

> FOR WING COMMANDER WHEELER. INFORMATION HERE THAT RHEINTOCHTER HAS SEVEN EACH NEW TYPE ROCKETS. ANTI AIRCRAFT ROCKETS SUPPOSED TO USE PROXIMITY FUZE. SIGNAL ALLSTONT [?] AND LOCATION FOR AIR LIFT BY OUR AIRCRAFT.

In 1946, the U.S. Army Ordnance Department reported [https://digitalcommons.unl.edu/cgi/viewcontent.cgi?article=1059&context=dodmilintel]:

> In connection with the subject of proximity fuzes, the Germans had expended a vast amount of energy on the research and development of fuzes which would detonate ammunition without coming in physical contact with the target. We were far ahead of them on actually getting a proximity fuze into production and into active use during the war, they were very effective, particularly in antiaircraft use. However, at the time the war ended, the German research and development had progressed to such an extent

> that they had designs almost ready for production and had thoroughly investigated many of the possible types of proximity fuzes; e.g. acoustic, radio, photo-electric and electro-static types. [...]
>
> A number of rocket propelled missiles which could be guided from the ground and which would detonate by the use of a proximity fuze when coming within the danger area of one of our airplanes were developed to the production stage and one guided missile was actually in production at the end of the war. Our understanding of the way one was to have operated was by means of radar screen which could track both the target and the missile. The operator would have the necessary controls required to direct the missile and by watching the radar screen could take the necessary steps to bring the missile as close as possible to the airplane, at which time the proximity fuze would function and the airplane would disappear.

See also the statements of Hermann Goering (pp. 5200–5202).

The United States and United Kingdom developed a simple radar proximity fuse for artillery shells and employed it effectively for anti-aircraft fire. Germany developed an enormous quantity and variety of proximity fuses and homing devices, many of which were more advanced than the Allied proximity fuse. Few of the German proximity fuses and guidance systems appear to have been deployed during the war, but that was due to Allied bombing of the factories where those systems were being produced, as well as some of the decisions (or indecision) of German political and military leaders, not due to any failures of German and Austrian scientists.

As shown in Fig. 6.225, Germany also created the first High-speed Anti-Radiation Missile (HARM), designed to seek and destroy enemy radar systems. At least 1,000 units of the Blohm & Voss BV 246 Hagelkorn with a Radieschen guidance unit on the front were produced by the end of the war, though apparently none were used in combat. An anti-radar version of the Henschel Hs 293 was also developed (p. 5411). The BV 246 Radieschen and anti-radar Hs 293 were the foundation for postwar HARM weapons in other countries.

Because the proximity fuses and homing devices developed in wartime Germany were so advanced and so diverse, immediately after the war, Allied countries confiscated the documentation, hardware, and scientists from those programs, and used them to produce proximity fuses and homing devices in the United States, United Kingdom, France, Soviet Union, and other countries during the postwar period. (See also Sections 6.6 and 9.6.)

6.9 Microscopes, Telescopes, and Other Optical Instruments

Creators from the predominantly German-speaking scientific world dominated the development of optical microscopy methods, from inventing the first known microscope to obtaining the maximum theoretical resolution from a microscope to developing fluorescence and phase contrast microscope approaches that are now used worldwide. They also invented and developed telescopes as well as other methods and applications of optics.[30]

The first known telescopes were produced around 1608 by creators such as Hans Lipperhey (German states/Dutch, 1570–1619), Jacob Metius (Dutch, ca. 1571–1628), and Zacharias Janssen (Dutch, ca. 1585–<1632). See Fig. 6.226.

As shown in Fig. 6.227, Antonie van Leeuwenhoek (Dutch, 1632–1723) created the first known microscope and used it to observe numerous types of single-celled and multicellular organisms. The American Council of Learned Societies summarized his discoveries [ACLS 2000, pp. 528–529]:

> Built his first microscope (1671), a minute lens, ground by hand from a globule of glass, clamped between two metal plates, with specimen holder affixed; went on to grind about 550 lenses; the best that has survived has a magnifying power of 270 and a resolving power of 1.4μ. Believed inorganic and organic nature are similar and that all living creatures are similar in form and function. In 1674, recognized that microorganisms are alive; communicated observations on these "little animals" to the Royal Society (1676), causing a sensation. Subsequently described bacteria, protozoa, rotifers, and ciliate reproduction. From study of spermatozoa, postulated that these penetrate the egg[...] Investigated the transport of nutrients in plants and animals[...]

Joseph von Fraunhofer (German states, 1787–1826, p. 853) made a number of important discoveries and inventions in optics. He invented diffraction gratings, and he studied the diffraction of light of different wavelengths. He used a diffraction slit and prism to develop a spectroscope, which he and others then applied to make important measurements in physics and chemistry. He also created achromatic (non-color-distorting) lenses and other specialized lenses that greatly improved the image quality for both telescopes and microscopes. Oxford University's *Biographical Dictionary of Scientists* explained how he combined and advanced both experimental and theoretical optics [Porter 1994, pp. 251–252]:

> [H]is work laid the basis for subsequent German supremacy in the making of high-grade scientific and optical instruments. [...]
>
> Although he had little formal education, Fraunhofer sought to understand optical theory and apply it to the practical work of constructing lens combinations of minimum aberration. At that time there was little high-quality crown and flint glass, and methods of determining the optical constants of glass were crude, limiting the size and quality of lenses that could be produced and also confining instrument makers to trial-and-error methods of construction. Fraunhofer approached lens-making according to optical theory and set out to determine the dispersion powers and refractive indices of different

> kinds of optical glass with greater accuracy. In collaboration with Guinand, he also sought to improve the quality of the glass used to make lenses.
>
> In 1814, Fraunhofer began to use two bright yellow lines in flame spectra as a source of monochromatic light to obtain more accurate optical values. Comparing the effect of the light from the flame with the light from the Sun, he found that the solar spectrum is crossed with many fine, dark lines. [...]
>
> In this way, Fraunhofer was able to make very accurate measurements of the dispersion and refractive properties of various kinds of glass, and in so doing he developed the spectroscope into an instrument for the scientific study of spectra.
>
> In 1821, Fraunhofer examined the patterns that result from light diffracted through a single slit, and related the width of the slit to the angles of dispersion of the light. Extending from a large number of slits, he constructed a grating of 260 parallel wires and made the first study of spectra produced by diffraction gratings. [...] By measuring the dispersion, he was able to determine the wavelengths of light of specific colours and the dark lines.
>
> Fraunhofer also constructed reflection gratings, enabling him to extend his studies to the effect of diffraction on oblique rays. By using the wave theory of light, he was able to derive a general form of the grating equation that is still in use today.

Simon Plössl (Austrian, 1794–1868) produced microscopes with achromatic objective lenses (Fig. 6.228). He also developed the now highly popular Plössl eyepiece design for telescopes, which offers an especially wide field of view.

Georg Johann Oberhäuser (German states, 1798–1868) and his successor Edmund Hartnack (German, 1826–1891) were other important early innovators in microscopy (Fig. 6.229). Edmund Hartnack produced the first water immersion lenses (putting a drop of liquid between the lens and the slide) to enable microscopes to see smaller details.

Carl Zeiss (German, 1816–1888, engineering and business), Ernst Abbe (German, 1840–1905, optical physics), and Otto Schott (German, 1851–1935, glass chemist) created and built up the Zeiss optical company, based in Jena, making it arguably the most advanced optical instrument company in the world. By the 1880s, they had perfected the diffraction-limited apochromatic microscope (Fig. 6.230), eliminating earlier flaws in lens design and glass composition in order to attain the maximum theoretical image resolution that can be achieved with visible light. That work remains the foundation of all modern optical microscope designs. They also developed a reputation for designing and manufacturing a wide range of other advanced optical instruments. The *Encyclopedia Britannica* explained some of the history [EB 2010]:

> Zeiss, Carl [...], German industrialist who gained a worldwide reputation as a manufacturer of fine optical instruments.
>
> In 1846 Zeiss opened a workshop in Jena for producing microscopes and other optical instruments. Realizing that improvements in optical instruments depended on advances in optical theory, he engaged as research worker Ernst Abbe, a physics and mathematics

lecturer (later professor) at the University of Jena, who in 1866 became Zeiss's partner. They engaged Otto Schott, a chemist, who developed about 100 new kinds of optical glass and numerous types of heat-resistant glass.

In the early 1900s, several scientists working at the Zeiss company made further significant advances in optical microscopy:

- In 1902, Richard Zsigmondy (Austrian, 1865–1929) and Henry Siedentopf (German, 1872-1940) invented the ultramicroscope for determining particle sizes in colloids; see Fig. 6.231.
- August Köhler (German, 1866–1948) and Moritz von Rohr (German, 1868–1940) invented the ultraviolet microscope in 1904, as shown in Fig. 6.232.
- August Köhler and Henry Siedentopf invented the fluorescence microscope in 1908 (Fig. 6.233). Fluorescence microscopes are now a widespread tool in biology laboratories because different cellular components can be labeled with different colors of fluorescent tags.

A Mach-Zehnder interferometer splits light into two beams, which travel different paths through transparent objects and then recombine, resulting in constructive and destructive interference patterns that can provide useful information about the objects (Fig. 6.62). Karl Bratuschek (German, 1865–1913) at the Zeiss company began trying to apply that same principle to microscopes but died before he could finish [Wimmer 2017]. Frits Zernike (Dutch, 1888–1966) continued that work and created the first phase contrast microscopes (1933), which were then mass-produced by Zeiss (pp. 1274, 2474–2484). Phase contrast microscopes make cells easily visible without having to add colored chemical stains. The chemical staining steps are not only cumbersome, but would usually kill the cells, so phase contrast microscopes are now a ubiquitous tool in biology laboratories worldwide to observe living cells. For the development of phase contrast microscopy, Frits Zernike won the Nobel Prize in Physics in 1953. Professor E. Hulthén of the Nobel Committee for Physics explained Zernike's work and noted how it built upon the earlier discoveries of Zeiss scientists such as Ernst Abbe [https://www.nobelprize.org/prizes/physics/1953/ceremony-speech/]:

> Probably no other instrument has been the object of so much technical and theoretical study as the microscope. The thorough theoretical foundation that we owe to the genius of Ernst Abbe of the famous Zeiss concern was followed at the end of the last century by a development of the microscope that brought its optical and illumination system very close to perfection.
>
> But even Abbe's theory had a gap, for it took into account only those conditions in which the microscopic objects appear against the background as a result of their contrasts in colour and intensity. Many microscopic objects, however, micro-organisms such as bacteria and cells, are colourless and transparent, and for this reason difficult to distinguish from their surroundings. Attempts have been made to overcome this difficulty with various methods of staining or with a special illumination system, the so-called darkfield illumination. The staining methods are not always suitable, as for example when we are dealing with living objects; and dark-field illumination easily leads to a misinterpretation of the finer details in the structural picture.
>
> It was this gap in Abbe's theory that in the 1930's led Zernike to re-investigate the refraction processes in the light that give rise to the image in a microscope. Even if

> the eye is not able to discern the change undergone by a beam of light when it passes through a transparent object, the change does nonetheless exist as a phase-difference of a quarter of a wavelength relative to the direct beam that does not pass through the object. The problem was thus to transform these otherwise imperceptible phase differences to visible contrasts in intensity. Zernike was able to show that this was possible, thanks to the fact that the two rays of light take different routes through the microscope before being reunited in the image. By interposing in the paths of the direct ray a so-called "phase-plate" which either further increases the phase-displacement to half a light-wavelength or smooths it out completely, Zernike attained the desired effect, so that the two rays either extinguish or reinforce each other. In this way the formerly invisible particle appears in dark or light contrast to the surroundings.
>
> I have deliberately dwelt upon the description of the phase-contrast microscope as the result of Zernike's method which is, so far, the most valuable. The phase-contrast method has, however, many other and increasingly important applications in optics. In addition to its capacity to render colourless and transparent objects visible in the microscope, it also enables one to detect slight flaws in mirrors, telescope lenses, and other instruments indispensable for research. In this connection, Zernike's phase-plate serves as an indicator which locates and measures small surface irregularities to a fraction of a light-wavelength. This sharpness of depth is so great that it penetrates to the point at which the atomic structure of the substance begins to become manifest.

Phase-contrast microscopy was adopted by Allied countries after they discovered some of the Zeiss phase-contrast microscopes at the end of World War II [FIAT 1059; pp. 2474–2484].

Carl Kellner (German states, 1826–1855), Ernst Leitz I (German, 1843–1920), and the son Ernst Leitz II (German, 1871–1956) created what came to be called the Leitz optical instrument company, which roughly paralleled the history and accomplishments of the Zeiss company. See Fig. 6.235.

- Ernst Arbeit (German, 18??–19??), Carl Metz (German, 18??–19??), and Felix Jentzsch (German, 18??–19??) developed microscopes at the Leitz company; see Fig. 6.236.

- In 1913, Oskar Barnack (German, 1879–1936) invented the first modern 35 mm still camera, which later was dubbed Leica (for Leitz Camera); see p. 637.

As shown in Fig. 6.237, John Jacob (Johann Jakob) Bausch (German, 1830–1926), Henry Lomb (German, 1828–1908), and Ernst Gundlach (German, 1834–1908) produced microscopes and other optical instruments at the Bausch & Lomb company in the United States.

In 1930, Bernhard Schmidt (German, 1879–1935) invented the Schmidt combination telescope and camera, which was adopted worldwide (Fig. 6.238). Oxford University's *Biographical Dictionary of Scientists* explained Schmidt's optical innovations [Porter 1994, p. 608]:

> After graduating in 1904 he stayed in Mittweida making lenses and mirrors for astronomers. One of his early accomplishments, in 1905, was a 40-cm/27-in mirror for the Potsdam Astrophysical Observatory. Schmidt worked independently, producing optical equipment of very high quality until 1926, when Schorr, the Director of the Hamburg Observatory, asked him to move into the Observatory and work there. Schmidt accepted the invitation. He worked on the mountings and drives of the telescopes, as well

> as on their optics. It was in Hamburg that he perfected his lens and built it into the Observatory telescope, specifically for use in photography. [...]
>
> It is usual for reflecting telescopes to have parabolic mirrors, rather than spherical ones; spherical ones are subject to an optical distortion known as spherical aberration. Parabolic mirrors too, however, suffer from their own optically distortive effect, 'coma'; but they provide an image that is at least centrally clear and focused. What Schmidt devised was a means of correcting the image formed by a spherical mirror—a disc-shaped lens thicker at the centre and edges than at half-radius. By replacing the parabolic mirror of a telescope with a spherical one plus his lens—his 'corrector plate', as he called it—he could produce an image that was sharply focused at every point (generally on a curved photographic plate, although on later models Schmidt used a second lens to compensate for the use of a flat photographic plate).

As illustrated in Fig. 6.239, Walther Bauersfeld (German, 1879–1959) developed the Zeiss planetarium projector Mark I (begun in 1912, delayed by World War I, and completed in 1923), Mark II (1930), and later models. Such planetarium projectors were adopted and used worldwide.

Wilhelm Schnittger (German, 19??–19??) invented advanced theodolites and cinetheodolites at Askania Werke in 1933 (Fig. 6.240). Askania instruments were used to monitor, measure, and guide test flights of A-4 (V-2) rockets and other aerospace vehicles during World War II. After the war, Askania theodolites were used for decades to track and film rockets and aircraft in the United States (Fig. 6.241). Askania instruments were also used by the Soviet Union and other countries after the war (e.g., pp. 2808, 3998, and 5535).

Alexander (or Olexander) Smakula (Austro-Hungarian, educated and worked in Germany, 1900–1983) invented antireflective coatings for lenses at Zeiss in 1935 (Fig. 6.242). His antireflective coatings were widely used in Germany during World War II. After the war, Allied investigators studied and copied Smakula's information on antireflective coatings, and he continued his work in the United States. Antireflective coatings have been used worldwide since then. For more information on the postwar transfer of this technology, see for example:

> BIOS 1183. *Anti-Reflection Surfaces on Glass, Optical Cements & Etching Resist for Fine Lines.*
>
> BIOS 1215. *German Methods of Rhodiumizing, Aluminizing, Anti-Reflection Surface Coating and Allied Subjects.*
>
> NavTecMisEu 461-45. *Methods of Film Coating for Low Reflection in the German Optical Industries.*

Marga Faulstich (German, 1915–1998) at the Schott glassworks developed improved optical lenses, incorporating not only Smakula's antireflective coatings but also new high-index-of-refraction materials such as Schwerflint 64 to make much thinner, lighter lenses for eyeglasses and other applications (Fig. 6.243).

After World War II, German high-quality plastic lenses and the technology to produce them were taken by the United States and directly copied by U.S. companies [NARA RG 40, Entry UD-75, Box 58, Folder Budget]. See Fig. 6.244.

Likewise, German optical and electron microscopes were seized by the United States and copied by U.S. companies [NARA RG 40, Entry UD-75, Box 58, Folder TIID Discards]. See Fig. 6.245.

German-speaking scientists even created gastroscopes or endoscopes that were appropriated by Allied countries after the war. For example, BIOS 874, *Computing and Testing Methods in the German Optical Industry*, p. 13, reported:

> [G. Wolf G.m.b.H. Berlin, a Zeiss subsidiary:] Probably the most interesting instrument is the Schindler flexible gastroscope, six to eight of which are being made monthly; thirty-eight glass elements are employed in the periscopic train, of which thirty-two are in the flexible portion, and a front negative lens is fitted to increase the visible field of view to 90^o. “Blooming” of the glass elements has not been tried.

Verfahren zur Beobachtung mit Phasenkontrast

Patentiert im Gebiet der Bundesrepublik Deutschland vom 31. Dezember 1948 an
Patentanmeldung bekanntgemacht am 31. Januar 1952
Patenterteilung bekanntgemacht am 24. Juli 1952
Die Priorität der Anmeldungen in den Niederlanden vom 25. November 1947 und
in den V. St. v. Amerika vom 12. Mai 1948 ist in Anspruch genommen

Die Erfindung betrifft eine Weiterbildung des von Zernike angegebenen Verfahrens zur Beobachtung mit Phasenkontrast von nicht oder wenig absorbierenden Objekten, insbesondere von mikroskopischen Objekten.

Um derartige Objekte sichtbar zu machen, war man früher gezwungen, sie zu färben, wodurch die Beobachtung lebender Objekte erschwert war. Die ungefärbten Objekte beeinflussen meistens nicht die Amplituden des sie durchsetzenden Lichtes, wohl aber in an sich nicht sichtbarer Weise die Phasen desselben. Sie bilden eine Phasenstruktur im Gegensatz zu der Amplitudenstruktur absorbierender Objekte.

Durch das Phasenkontrastverfahren gelingt es, Phasenstrukturen in derselben Weise sichtbar zu machen wie Amplitudenstrukturen. Das Verfahren beruht bekanntlich darauf, daß ein Teil des das Objekt durchlaufenden Lichtes eine Phasenänderung von vorzugsweise 90° gegenüber den vom Objekt abgebeugten anderen Teil des Lichtes erhält, indem es eine sogenannte Phasenschicht durchläuft, welche ihm eine Phasenänderung erteilt. Auf diese Weise erscheint eine Phasenstruktur wie eine Amplitudenstruktur und umgekehrt.

Bezeichnet man den Brechungsindex der Phasenschicht mit n_s, ihre Dicke mit d, so wird die Schicht so ausgebildet, daß $\frac{\lambda}{4} = (n_s - 1)\, d$ ist.

Diese Bedingung ist mit einer bestimmten Schicht nur für eine Wellenlänge genau erfüllbar, weil der Brechungsindex im Falle normaler Dispersion mit wachsender Wellenlänge abnimmt. Daher überlagern sich dem Phasenkontrastbild in

THEODOLITE

Wilhelm Schnittger, Berlin-Wilmersdorf, Germany, assignor to Askania-Werke A. G., a corporation of Germany

Application July 13, 1939, Serial No. 284,336
In Germany February 18, 1933

9 Claims. (Cl. 88—2.7)

This application is a continuation-in-part of the application Ser. No. 106,419.

This invention relates to theodolites, more particularly to instruments of the type being fixed in azimuth having a horizontal major axis and a minor axis which is disposed at right angles to said major axis.

An object of this invention is to provide an instrument having a simple construction and offering an unobstructed, wide field of view for one or two observers.

Another object of this invention is to provide an instrument permitting two observers simultaneously to observe the same field of view without impeding each other.

Further aims, objects, and advantages of this invention will appear from a consideration of the description which follows with the accompanying drawings, showing embodiments of this invention for illustrative purposes. It is to be understood, however, that the description is not to be taken in a limiting sense, the scope of this invention being defined in the appended claims.

Referring to the drawings:

Fig. 1 is a side elevation of a theodolite embodying the invention.

Fig. 2 is a plan view of the instrument, shown in Fig. 1.

Fig. 3 shows in detail a gear for adjusting an erecting prism of the theodolite, shown in Figs. 1 and 2.

Fig. 4 is a front elevation of another embodiment of this invention.

Fig. 5 is a side elevation of the instrument, shown in Fig. 4.

Fig. 6 shows diagrammatically a plan view of an optical system of the theodolite.

Fig. 7 is an elevation of the system, shown in Fig. 6, a section being taken on line 2—2.

Fig. 8 is a side elevation of an instrument having an optical system according to Figs. 6 and 7.

Fig. 9 is the front elevation of the instrument, shown in Fig. 8.

Fig. 10 is a side elevation of another embodiment of this invention.

In the embodiment, shown in Figs. 1 to 3, an instrument body **10** is mounted on a socket **11**. The body supports a casing **12** for tilting movement about a horizontal major axis **3—3** relatively to the body. The tilting movement of the casing **12** is controlled by manual means, a hand wheel **13** and a gearing being shown for this purpose. The shaft **14** of the hand wheel is mounted for rotation and axial displacement in a socket **11** to enable gears **15** and **16** to be brought into engagement with gears **17** and **18** of a second shaft **19**. In the inward position, shown in the drawings, the gears are in such engagement as to move the shaft **19** relatively slowly. A further shaft **20** mounted in bearings **21** and **22** is connected to the shaft **19** by means of the bevel gears **23** and **24** and drives a worm **27** meshing with a large worm wheel **28** for tilting the casing **12**. The tilt of the casing may be read on a coarse graduation **29** and a fine graduation **30**, the latter being arranged on a disk revolving with the worm **27**.

In the casing **12** a support **31** is mounted for tilting movement about a minor axis **4** spaced from the major axis **3—3** in a vertical direction and disposed at right angles to said major axis. The support **31** carries a double reversing prism **32** forming a part of an optical system of the instrument later to be described. A blinder-tube **33** may be provided for the prism. The inclination of the support **31** may be read on a scale **34**.

For controlling the inclination of the prism or support a second hand wheel **35** is provided connected therewith by means of suitable motion transmitting devices. In the illustrative example repeater motors are shown for this purpose. A first motor **36** is operated from the hand wheel **35** over a variable transmission gear **37**, **38**, **39**, **40** and shafts **41** and **42**. The second repeater motor **43** in the casing **12** is connected to the first motor by means of conductors **44**. The second repeater motor **43** drives a shaft **45** carrying a worm **46** which meshes with the worm wheel **47**.

Rays of light entering the instrument in the direction of the arrows **48** pass through the double reversing prism **32** and lenses **49** to be deflected into the direction of the major axis **3—3** by means of a reflecting surface, a prism **50** being shown for this purpose. From the prism **50** the light passes through a reticle **51** which is shown as being illuminated by means of an electrical bulb **52** transmitting its light through a prism **53**. In the path of parallel light rays between further lenses **54**, **55** an erecting prism **56** is arranged. At the ocular end of the instrument an eye-piece **65** may be provided for the observer.

As shown in Fig. 3 the erecting prism **56** is arranged to be rotatable about half the tilting angle of the casing **12** relatively to the body **10**. In the illustrated example a supporting tube **57** for the erecting prism is rotatably mounted in a second tube **58** rigidly connected to the large worm gear **28**. Gears **59** and **60** are provided on the tubes **58**, **57**, respectively. Further gears **61** and **62**

Einrichtung zur Ermittlung der Geschwindigkeit von schnellbewegten Objekten, insbesondere Flugzeugen, auf photographischem Wege

Patentiert im Deutschen Reich vom 7. Mai 1939 an

Patenterteilung bekanntgemacht am 25. November 1943

Die Erfindung bezieht sich auf eine Einrichtung zur Ermittlung der Geschwindigkeit von schnell bewegten Objekten, insbesondere Flugzeugen, auf photographischem Wege mittels zweier an den Endpunkten einer Meßstrecke aufgestellter, fest ausgerichteter kinematographischer Aufnahmekameras, bei der zusammen mit der Zielbildaufnahme eine laufende Zeitzeichenregistrierung erfolgt und der Beginn des Registriervorganges auf den Filmbildern markierbar ist.

Die bekanntgewordenen Meßeinrichtungen dieser Art weisen den großen Nachteil auf, daß keine üblichen kinematographischen Aufnahmekameras benutzt werden können, sondern besonders ausgebildete Spezialkameras erforderlich sind, in denen unter anderem besondere Organe (Stimmgabeln, Galvanometerspiegel usw.) für die Zeitregistrierung sowie gleichzeitig betätigbare Verschlüsse für den gleichzeitigen Einsatz der Zeitregistrierung in den Kameras vorzusehen sind. Ein weiterer Nachteil dieser bekannten Meßeinrichtung besteht darin, daß beide Aufnahmekameras während der ganzen Messung ständig laufen müssen, damit die Auswertung der registrierten zeitlichen Durchgänge durch die beiden Endpunkte der Meßstrecke an Hand der zur gleichen Zeit auf den beiden Filmstreifen erfolgten laufenden Zeitregistrierung möglich ist. Dies will besagen, daß die eine Kamera auch dann, wenn der Durchgang des Aufnahmeobjektes durch den Standort dieser Kamera bereits erfolgt ist, noch so lange weiterlaufen muß, bis der Durchgang des Aufnahmeobjektes durch den Stand-

Patentiert im Deutschen Reich vom 18. Mai 1939 an
Patenterteilung bekanntgemacht am 17. August 1944

Es ist bekannt, daß man die Güte der von einem optischen System erzeugten Bilder durch zusätzliche Mittel verbessern kann, durch welche die das optische System durchsetzenden Wellen im Sinne einer Schwächung des Lichts von der Mitte nach dem Rande des diese Mittel enthaltenden optischen Elementes des Systems zu inhomogenisiert werden, wobei das genannte optische Element auch von einer oder mehreren zusätzlich zum optischen System hinzugefügten planparallelen Platten od. dgl. verkörpert sein kann. Diese Maßnahme hat die Wirkung, daß die Intensität der Beugungsfiguren, die mit Hilfe der äußeren, d. h. achsenferneren Teile des Systems von einem als Objekt dienenden Lichtpunkte erzeugt werden, im Verhältnis zur Intensität derjenigen Beugungsfiguren dieses Lichtpunktes geschwächt wird, die mit Hilfe der mittleren, d. h. achsennäheren Teile erzeugt werden. Die Verbesserung der Bildgüte beruht darauf, daß in der Abbildung des Lichtpunktes, die durch Übereinanderlagerung der verschiedenen Beugungsfiguren entsteht, die Intensitätsanteile, die aus achsennahen Teilen des Systems herrühren, verhältnismäßig stärker wirksam sind als die Intensitätsanteile aus den Randteilen. Die Gesamt-

Optischer Teil, der gemäß dem Verfahren nach Patent 685 767 mit einer die Reflexion vermindernden Schicht versehen ist

Zusatz zum Patent 685 767
Patentiert im Deutschen Reich vom 28. März 1937 an
Das Hauptpatent hat angefangen am 1. November 1935
Patenterteilung bekanntgemacht am 2. November 1944

Im Hauptpatent 685 767 ist ein Verfahren angegeben, um die Reflexionsverluste, die beim Durchgang des Lichtes durch einen optischen Teil auftreten, bis auf etwa das 0,005fache des einfallenden Lichtes zu vermindern. Dieses Verfahren besteht darin, daß die Grenzflächen des optischen Teils mit einer zusätzlichen Schicht eines anderen Stoffes mit einem kleineren Brechungsexponenten, als der optische Teil hat, versehen werden. Es hat sich jedoch gezeigt, daß die damit erreichte Reflexionsverminderung in der Regel nicht dauernd erhalten bleibt, da die Metallteile, in denen der optische Teil gefaßt ist, gewöhnlich eingefettet sind, was zur Folge hat, daß das Fett im Laufe der Zeit über die zusätzliche Schicht wandert und sich außerdem auf dieser Schicht Fettdämpfe niederschlagen. Der so entstehende fettige Belag ändert die Brechungsverhältnisse in der Grenzzone zwischen der Luft und dem optischen Teil in dem Sinn, daß sich die Reflexionsverluste wiederum vergrößern.

Die Erfindung geht aus von einem optischen Teil, der gemäß dem Verfahren nach Patent 685767 mit einer die Reflexion vermindernden

Verfahren zur Veränderung der Reflexion von Körpern aus organischem Kunststoff

Patentiert im Gebiet der Bundesrepublik Deutschland vom 22. Oktober 1944 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 30. Oktober 1952
Patenterteilung bekanntgemacht am 28. Mai 1953

Die Erfindung betrifft ein Verfahren zum Erzeugen einer Schicht von erhöhter Reflexion auf einem Körper aus organischem Kunststoff, insbesondere aus einem Vinylharz, einem Akrylharz, aus Cellulose oder einem ähnlichen Kunststoff. Es liegt nahe, in der bei Glas bekannten Weise den Körper dadurch mit einer solchen Schicht zu versehen, daß man einen Stoff von höherer Brechungszahl auf ihn aufbringt, z. B. indem man diesen aufdampft. Die mit einer dauerhaften Aufbringung verknüpften Umständlichkeiten kann man vermeiden und zugleich eine besonders dauerhafte Schicht erzielen, wenn man nach der Erfindung die Schicht aus dem betreffenden organischen Kunststoff selbst heraus bildet, indem man den betreffenden Körper, als Anode geschaltet, einer Glimmentladung aussetzt; es bildet sich dadurch eine dauerhafte Schicht von erhöhter Reflexion. Die Dicke der so gebildeten Schicht hängt von der Spannung und der Stromstärke der Glimmentladung sowie von deren Zeitdauer ab. So kann man z. B. bei einer Spannung von 3000 V und einer Stromdichte von 0,05 mA/qcm durch eine Entladung von 5 Minuten die Reflexion von Körpern aus Polymethacrylsäureestern um 2% erhöhen.

Handelt es sich darum, die Reflexion von organischem Kunststoff zu vermindern, so ist auch hierfür das erfindungsgemäße Verfahren von Nutzen. Es ist zwar bekanntlich möglich, diese Verminderung durch Aufbringen einer Schicht eines Stoffes

Verfahren zur Erzeugung einer die Reflexion vermindernden Schicht auf der Oberfläche eines optischen Elementes und Gerät zur Ausübung des Verfahrens

Patentiert im Gebiet der Bundesrepublik Deutschland vom 13. Februar 1940 an
Patentanmeldung bekanntgemacht am 18. August 1955
Patenterteilung bekanntgemacht am 26. Januar 1956

Bekanntlich können die beim Lichtdurchtritt durch die Oberflächen optischer Elemente auftretenden Reflexionsverluste dadurch vermindert werden, daß man die Flächen mit einer dünnen Schicht bestimmter Stoffe belegt. Das Aufbringen solcher Schichten erfolgt zweckmäßig durch Aufdampfen der Stoffe im Vakuum. Unter der Voraussetzung, daß die Lichtstrahlen im rechten Winkel zur Fläche einfallen, ergibt sich die maximale Reflexionsverminderung, wenn die folgenden Gleichungen erfüllt sind:

$$n_s = \sqrt{n} \qquad (1)$$

$$d \doteq (2x-1)\frac{\lambda}{4n_s}. \qquad (2)$$

In diesen Gleichungen bedeuten: n_s die Brechungszahl des aufgedampften Stoffes, n die Brechungszahl des optischen Elementes, d die Schichtdicke, x eine ganze positive Zahl und λ die Wellenlänge des Lichtes.

Aus den Gleichungen geht hervor, daß für Lichtstrahlen, die unter gleichen Winkeln einfallen, die Schicht eine über die ganze Lichtdurchtrittsfläche gleiche Dicke haben muß, wenn die maximale Reflexionsverminderung erreicht werden soll. Diese Forderung läßt sich leicht erfüllen, wenn die zu belegende Fläche eine konkave Fläche ist, indem man die Verdampfungsstelle im Krümmungsmittelpunkt der Fläche anordnet. Ist die zu belegende Fläche eben, dann ergibt sich beim Verdampfungs-

Optisches Glas

Patentiert im Gebiet der Bundesrepublik Deutschland vom 11. Februar 1954 an
Patentanmeldung bekanntgemacht am 9. August 1956
Patenterteilung bekanntgemacht am 24. Januar 1957

Die Erfindung bezieht sich auf ein optisches Glas, welches derart zusammengesetzt ist, daß es eine hohe Brechungszahl n_d aufweist, die größer als 1,745 ist, und welches eine beträchtlich geringere Lichtstreuung besitzt als die üblichen Schwerflintgläser.

Es sind Gläser dieser Art bekannt, die in der Hauptsache aus Bleiphosphat bestehen. Diese Gläser sind zwar durchaus farblos, jedoch so weich, daß ihre Verwendung für optische Zwecke nur bedingt möglich ist.

Es sind auch schon harte Gläser mit hoher Brechungszahl vorgeschlagen worden, die unter Verwendung großer Mengen von seltenen Erden gemeinsam mit Tantal oder Niob und Borsäure erschmolzen wurden. Diese Gläser sind jedoch sehr kostspielig.

Hochbrechende Gläser mit mittlerer Streuung wurden auch durch Zusätze von Cadmiumoxyd erhalten. Die Verwendung von Cadmiumoxyd ist jedoch ebenfalls verhältnismäßig kostspielig und zudem wegen seiner großen Giftigkeit bei der Handhabung unerwünscht.

Bekanntgeworden sind auch Gläser des Systems PbO-ZnO-B_2O_3. Diese Gläser haben sich aber für die Herstellung von optischem Glas als völlig ungeeignet erwiesen, da sie wegen ihrer äußerst geringen Viskosität bei der Gußtemperatur zu

Glas für technische, insbesondere optische Zwecke

Patentiert im Gebiet der Bundesrepublik Deutschland vom 6. Juli 1955 an
Patentanmeldung bekanntgemacht am 6. September 1956
Patenterteilung bekanntgemacht am 14. Februar 1957

Die Erfindung bezieht sich auf ein Glas, welches für technische, insbesondere optische Zwecke bestimmt ist.

Die bekannten höher brechenden Gläser, die optische Werte für $n_D = 1{,}610$ bis $1{,}675$ und für $\nu = 50$ bis 44 aufweisen und als Barytflintgläser bezeichnet werden, enthalten größere Mengen an Bleioxyd und besitzen deshalb den Nachteil einer deutlich gelben Färbung.

Es wurde nun gefunden, daß man diese Färbung vermeiden kann und Gläser gleicher optischer Lage mit besonders vorteilhaften Eigenschaften erhält, wenn diese auf Aluminatbasis aufgebaut sind.

Erfindungsgemäß bestehen die Gläser zu mindestens 45 % aus Aluminiumoxyd, 25 bis 45 % aus Erdalkalien sowie 1 bis 17 % aus Alkalien. Der Rest kann durch SiO_2, GeO_2, ZnO, Bi_2O_3, La_2O_3, Ta_2O_5 oder ZrO_2 gebildet werden. Erfindungsgemäß werden die genannten Zusätze in folgenden Grenzen gehalten:

SiO_2 oder GeO_2	0 bis 15 %
MgO	0 bis 5 %
SrO und BaO	0 bis 12 %
ZnO	0 bis 4 %
Bi_2O_3, La_2O_3, Ta_2O_5, ZrO_2	0 bis 5 %

Von den Alkalien sind vorzugsweise 1 bis 7 % als Lithiumoxyd eingeführt. Besonders günstige Schmelz-

PLASTIC LENS

The attached exhibit is a small plexiglas lens for use in opitcal instruments such as microscopes, cameras, and similar equipment.

The unique feature of this lens is that it was cut with a diamond tool from a heat-stablized plastic bar on a common spherical turning lathe. Such a lens was produced by the Germans at the rate of 4-5 per minute. This method of production eliminated the thermal and polymerization strains present in the blown, cast or pressed American lenses. These strains always effect the optical excellence of the finished product. Machining a lens from a heat treated bar eliminated this difficulty.

A development which had not yet reached production involved the cutting of non-spherical lenses for special purposes. Thus it would be possible to make certain corrections for normal optical distortion during the cutting of a lens for a particular purpose.

This item was picked up at the Walter Kopperschmidt Werke at Blumberg in southern Germany. It is reviewed by George Beiser in his report entitled "Plastic Aircraft Tooling and Tooling for Transparent and Optical Plastics", JIOA-71.

MICROSCOPES

Investigators of the Technical Equipment Section have discovered that the Germans have made remarkable progress in the field of microscopy as a result of their wartime research activities.

An interference microscope which was developed by the Carl Zeiss Company and which permits optical detection of interferences of twenty millionths of an inch in surface finishes has been evacuated to this country for exploitation by American industry. Domestic optical equipment manufacturers have expressed a keen interest in this device which is remarkably ingenious in that it employs the measurement of the interference of light beams caused by imperfections in surface finishes to indicate the depth of such imperfections in the surface being examined.

A phase-contrast microscope which permits the examination of biological specimens without staining or otherwise injuring the specimens has also been evacuated to this country for test and research purposes. The American optical industry and the National Bureau of Standards are very much interested in this device for there had been no such instrument available in this country prior to the discovery of the instrument produced by the Germans.

An electro-static electron microscope which had been used for developmental work at the A.E.G. Farben experimental laboratories at Helmsbrecht was discovered at the Kaiser Wilhelm Institute at Ochstadt. One of these instruments is being evacuated to the Naval Research Laboratory where it will be set up for inspection by American industry. Prior to the discovery of this instrument there had been no such instrument available in this country. On the basis of information which has been obtained thus far, indications are that this microscope will prove to be extremely valuable in cellular research. Consequently, there is reason to believe that it will contribute to a considerable extent in the work that is being done in this country in cancer research.

Information pertaining to the electro-static electron microscope is contained in Report No. PB-44667 published by the Office of Technical Services of the Department of Commerce.

6.10 Electron Microscopes

Ordinary light microscopes use light waves to visualize objects. Visible light has wavelengths in the range of 400–700 nanometers, so it cannot image objects that are much smaller than those wavelengths. The minimum visible size is a little less than one hump of the wave, or a little less than half the wavelength, roughly 150 nanometers at the smallest. For comparison, most viruses are $\sim$ 20–150 nanometers wide, and individual atoms are $\sim$ 0.1–0.5 nanometers wide, so objects from atoms to viruses cannot be seen with light microscopes.

From quantum physics, small particles such as electrons can also behave like waves, and they can have wavelengths much smaller than those of light (p. 884). Moreover, one can build an electrostatic lens or a magnetic lens to focus a beam of electrons, just as a conventional optical lens can focus a beam of light (Fig. 6.246). Thus it is possible to build an electron microscope that uses electrostatic or magnetic lenses, fires a beam of electrons at tiny objects, collects the scattered electrons to detect the shape of the objects, and resolves objects far smaller than a light microscope could.

Just as most of the major developments in light microscopy and quantum physics came from the German-speaking world, most of the major innovations in electron microscopy also came from the German-speaking world, from the very first electron microscopes (Section 6.10.1) to electron microscopes powerful enough to see individual atoms (Section 6.10.2).[31] Electron microscopes have become indispensable for modern work in biology, materials science, microelectronics, and other fields.

6.10.1 Electron Microscopes and Scanning Electron Microscopes

As shown in Fig. 6.247, Hans Busch (German, 1884–1973) developed the first electrostatic and magnetic lenses for electrons in 1926. In 1928, Leo Szilard (Hungarian, 1898–1964) made the first known proposal to use such lenses to create an electron microscope.

Four different groups worked in parallel to build and demonstrate the world's first electron microscopes. All four groups were in the greater Berlin area:

1. A group at the Technische Hochschule Berlin produced electron microscopes from 1931 onward; see Fig. 6.248. The group included Max Knoll (German, 1897–1969), Bodo von Borries (German, 1905–1956), Ernst Ruska (German, 1906–1988), and Helmut Ruska (German, 1908–1973). Ernst Ruska played an especially large role in this group from the beginning, as well as later when this group closely collaborated with the Siemens & Halske group. Of all the earliest electron microscope builders, Ernst Ruska lived long enough to win the Nobel Prize in Physics in 1986. His brother Helmut took the first electron microscope

pictures of viruses (p. 200). Professor Sven Johansson of the Royal Academy of Sciences praised the surviving Ruska as well as the other original developers of electron microscopy [https://www.nobelprize.org/prizes/physics/1986/ceremony-speech/]:

> This new development was the electron microscope. The electron microscope is based on the principle that a short coil of a suitable construction, carrying an electric current, can deflect electrons in the same way that a lens deflects light. A coil can therefore give an enlarged image of an object that is irradiated with electrons. The image can be registered on a fluorescent screen or a photographic film. In the same way that lenses can be combined to form a microscope, it was found that an electron microscope could be constructed of coils. As the electrons used in an electron microscope have a much shorter wavelength than light, it is thus possible to reach down to much finer details. Several scientists, among them Hans Busch, Max Knoll, and Bodo von Borries, contributed to the development of the instrument, but Ernst Ruska deserves to be placed foremost. He built in 1933 the first electron microscope with a performance significantly better than that of an ordinary light microscope. Developments since then have led to better and better instruments. The importance, in many areas of research, of the invention of the electron microscope should, by now, be well known.

2. Siemens & Halske developed electron microscopes from 1931 onward, first independently and then in close collaboration with personnel from the Technische Hochschule Berlin group (Fig. 6.249). Siemens & Halske personnel included Reinhold Rüdenberg (German, 1883–1961), Ernst Lubcke (German, 1890–1971), Walter Glaser (Austrian, 1906–1960), and Heinz-Otto Müller (German, 1911–1945).

3. A group at Allgemeine Elektrizität Gesellschaft (AEG) developed electron microscopes from 1931 onward, as shown in Fig. 6.250. The group included Hans Boersch (German, 1909–1986), Ernst Brüche (German, 1900–1985), A. Jakob (German?, 19??–19??), E. Johannson (German?, 19??-19??), Hans Mahl (German, 1909–1988), Carl Ramsauer (German, 1879–1955), and Otto Scherzer (German, 1909–1982).

4. Manfred von Ardenne (German, 1907–1997) created the first scanning electron microscope in 1937, and continued to develop electron microscopes after that. See Fig. 6.251. At the end of World War II, von Ardenne moved to the Soviet Union; he was awarded a Stalin Prize for building electron microscopes there.

APPARATUS FOR PRODUCING IMAGES
OF OBJECTS

Reinhold Rüdenberg, Berlin-Grunewald, Germany, assignor to Siemens-Schuckertwerke Aktiengesellschaft, Berlin-Siemensstadt, Germany, a corporation of Germany

Application May 27, 1932, Serial No. 613,857
In Germany May 30, 1931

12 Claims. (Cl. 250—27.5)

My invention relates to apparatus for producing images of objects.

Owing to the fact that in fieldless spaces electron rays travel, similar to light rays, in straight paths, an object impervious to the rays, when placed in a divergent bundle or beam of rays, produces an enlarged shadow on a fluorescent screen onto which the rays are projected.

In cathode-ray oscillographs, electro-magnetic fields surrounding the beam concentrically and causing a stricture of the beam are often employed. These fields have an effect on a beam of rays similar to that of an optical lens on a beam of light; they may cause the rays of the beam to become convergent or divergent. Consequently, with such stricture fields an enlarged or a reduced luminous image of the cathode ray beam is, according to circumstances, also obtained on the fluorescent screen.

This enlargement or magnification of shadows has hitherto been regarded only as a secondary phenomenon of minor technical importance in the use of electron rays. The reduction has in the past only been employed to obtain a sharply defined luminous spot (focus).

According to my invention, the effect, similar to that of lenses in optics, produced by fields of force surrounding concentrically a beam of electrons and exerting a radial influence on same, is utilized for enlarging objects in a manner corresponding to that obtained with optical magnifying glasses and microscopes. For this purpose the object to be enlarged is exposed to an electron ray or a beam of rays, and before or behind the object, the beam is by means of lens-like acting fields made convergent or divergent.

In Figures 1 to 5 of the drawings the principle of the invention is explained. Figures 6 to 11 illustrate various manners of carrying out the invention.

Fig. 1 shows a magnetic stricture coil, the length of which is small compared with the length of the path of the beam of rays. The rays are forced by the magnetic field toward the axis of the coil, coinciding with the axis of the beam, so that the rays meet in a focal spot or a focal

of force. The charge on the stop *a* is assumed to be negative. When the electrons of a beam or bundle of cathode rays pass through the stop they are repelled by same. They are, therefore, deflected from their original paths, which are assumed to be parallel, towards the center and are assembled to a convergent beam meeting in the focal point 0, beyond which they then diverge. As the radial component of the field strength of the stop is zero in its axis and increases outwardly in linear proportion to the distance, the degree of deflection of the electron rays also increases with the distance from the beam and stop axis. This causes all the rays to meet in the same focal spot. To obtain with sufficient accuracy this proportional relation of the radial field strength to the distance from the axis, it is advisable to make the opening of the stop considerably larger than the diameter of the original beam, or, by choosing a special shape for the electrodes, to give the field the suitable shape.

If the potential of the diaphragm is assumed to be positive instead of negative, the electron rays will be attracted by the stop. The rays of the beam which till then were moving in parallel paths now become divergent, as shown in Fig. 3. The negative stop, therefore, has the same effect as a convex lens in optics, and the positive stop has that of a concave lens. By combining stops of that kind, all the devices known in optics and based on converging or diverging beams can be imitated for electron rays. It is in this manner possible, for example, to make a microscope or a telescope for use with direct or reflected electron rays, by proportioning the relative distances between the object, the diaphragm or stop and the projection screen in accordance with the general optical formula

$$\frac{1}{a}+\frac{1}{b}=\frac{1}{f}$$

in which a represents the distance between the object and the lens (in this case the diaphragm), b the distance between the lens and the screen, and f the focal length of the lens (in the present case the distance at which the charged diaphragm brings the parallel beam to a focal point).

Manfred von Ardenne (1907–1997) Scanning electron microscope (1937)

Das Elektronen-Rastermikroskop.

Theoretische Grundlagen.

Von **Manfred von Ardenne.**

Mit 14 Abbildungen. (Eingegangen am 25. Dezember 1937.)

Das Prinzip des Elektronen-Rastermikroskops. Herstellung der Elektronensonde. Herstellung des Rasters. Die verschiedenen Beleuchtungsarten. Untersuchung von Objekten in Luft. Die Grenzen für das Auflösungsvermögen des Rastermikroskops. Intensitätsfragen und Auflösungsvermögen. Zusammenfassung.

In einer vorausgegangenen Arbeit[1]) über die Möglichkeiten des Elektronenmikroskops wurde nachgewiesen, daß der durch unterschiedliche Abbremsung der Elektronen in der Objektschicht und in der Objektträgerfolie verursachte chromatische Fehler bei der Untersuchung vieler mikroskopischer Objekte, insbesondere bei der Untersuchung von Mikrotomschnitten, das erreichbare Auflösungsvermögen stark herabsetzt. Nur bei Objektschichten, die nicht viel dicker sind als die kleinste ohne Objektsgeschwindigkeitsstreuung auflösbare Strecke, ist die volle Leistungsfähigkeit des Elektronenmikroskops gegeben. Auf Grund der quantitativen Untersuchung dieser Zusammenhänge gelangte der Verfasser im Februar 1937 zu einem neuen Prinzip elektronenmikroskopischer Abbildung, bei dem neben anderen grundsätzlichen Vorteilen der chromatische Fehler durch Geschwindigkeitsstreuung der Elektronen im Objekt in Fortfall kommt.

Figure 6.251: Manfred von Ardenne created the first scanning electron microscope in 1937, and continued to develop electron microscopes after that.

6.10.2 Scanning Tunneling Electron Microscopes and Atomic Force Microscopes

Although somewhat later than the time period that is the main focus of this book, in 1981, a group at IBM Zurich developed scanning tunneling electron microscopes powerful enough to see individual atoms (Fig. 6.252), as well as closely related atomic force microscopes. The group included Heinrich Rohrer (Swiss, 1933–2013), Gerd Binnig (German, 1947–), Christoph Gerber (Swiss, 1942–), and Edmund Weibel (Swiss?, 19??–). Rohrer and Binnig won the Nobel Prize in Physics in 1986, sharing the stage with Ernst Ruska. Professor Sven Johansson of the Royal Academy of Sciences explained the importance of their work [https://www.nobelprize.org/prizes/physics/1986/ceremony-speech/]:

> A crystal surface which appears completely flat in a microscope is seen with this instrument to be a plain on which atoms rise like hills in a regular pattern.
>
> Attempts by Russell Young and co-workers to realize these ideas revealed enormous experimental difficulties. The scientists who finally mastered these difficulties were Gerd Binnig and Heinrich Rohrer. Here it was a question of moving the needle over the surface of the sample and registering its vertical position, with great precision and without disturbing vibrations. The data obtained are then printed out, in the form of a topographic map of the surface, by a computer. The investigation may be concerned with a crystal surface, whose structure is of interest in microelectronic applications. Another example is the investigation of the adsorption of atoms on a surface. It has also been found to be possible to study organic structures, for example, DNA molecules and viruses. This is just the beginning of an extremely promising and fascinating development.

Chapter 7

Creators and Creations in Mechanical Engineering

Fest gemauert in der Erden
Steht die Form, aus Lehm gebrannt.
Heute muß die Glocke werden.
Frisch Gesellen, seid zur Hand.
Von der Stirne heiß
Rinnen muß der Schweiß,
Soll das Werk den Meister loben,
Doch der Segen kommt von oben.

Zum Werke, das wir ernst bereiten,
Geziemt sich wohl ein ernstes Wort;
Wenn gute Reden sie begleiten,
Dann fließt die Arbeit munter fort.
So laßt uns jetzt mit Fleiß betrachten,
Was durch die schwache Kraft entspringt,
Den schlechten Mann muß man verachten,
Der nie bedacht, was er vollbringt.
Das ist's ja, was den Menschen zieret,
Und dazu ward ihm der Verstand,
Daß er im innern Herzen spüret,
Was er erschafft mit seiner Hand.

Nehmet Holz vom Fichtenstamme,
Doch recht trocken laßt es sein,
Daß die eingepreßte Flamme
Schlage zu dem Schwalch hinein.
Kocht des Kupfers Brei,
Schnell das Zinn herbei,
Daß die zähe Glockenspeise
Fließe nach der rechten Weise.

Walled up in the earth so steady
Burned from clay, the mould doth stand.
This day must the Bell be ready!
Fresh, O workmen, be at hand!
From the heated brow
Sweat must freely flow,
That the work may praise the Master,
Though the blessing comes from higher.

Our work in earnest preparation,
Befitteth well an earnest word;
When joined by goodly conversation,
Then flows the labor briskly forw'd.
So let us now with care consider,
What through a frail power springs forth:
The wicked man one must have scorn for,
Who ne'er reflects, what he brings forth.
This it is, what all mankind graceth,
And thereto his to understand,
That he in inner heart so traceth,
What he createth with his hand.

Take the wood from trunk of spruce tree,
Yet quite dry let it abide,
That the flame compressed so tightly
Strike the gullet deep inside!
Cook the copper brew,
Quick the tin in, too!
That the glutinous bell-metal
Flowing rightly then will settle!

Was in des Dammes tiefer Grube
Die Hand mit Feuers Hülfe baut,
Hoch auf des Turmes Glockenstube
Da wird es von uns zeugen laut.
Noch dauern wird's in späten Tagen
Und rühren vieler Menschen Ohr
Und wird mit dem Betrübten klagen
Und stimmen zu der Andacht Chor.
Was unten tief dem Erdensohne
Das wechselnde Verhängnis bringt,
Das schlägt an die metallne Krone,
Die es erbaulich weiterklingt.

What in the dam's dark cavern dour
The hand with fire's help did mould,
High in the belfry of the tower
There will our story loud be told.
Still will it last as years are tolling
And many ears will it inspire
And wail with mourners in consoling
And harmonize devotion's choir.
What here below to son terrestr'al
The ever-changing fate doth bring,
Doth strike the crown which made from metal,
Uplifting it doth sound its ring.

Friedrich Schiller. 1798. Das Lied von der Glocke [The Song of the Bell].
English verse translation by Marianna Wertz.

This chapter gives an overview of some innovations in mechanical engineering that have played major roles in the modern world and that were invented or discovered by scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries.[1]

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

For general overviews of large portions of the history of mechanical engineering in the German-speaking world, see: Buchheim and Sonnemann 1990; Bunch and Hellemans 2004; Cardwell 1995; Challoner 2009; Gööck 2000; Heckl 2010, 2011; Heßler 2012; Jankowsky 2000; König 2000, 2009; König and Schneider 2007; Ludwig 1974; Lundgreen and Grelon 1994; Radkau 1989, 2016; Technisches Museum Wien 2011; Weitensfelder 2009, 2013.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

Creators from the German-speaking world made major contributions to:

- 7.1. Writing and printing technology
- 7.2. Musical instruments
- 7.3. Internal combustion engines and motor vehicles
- 7.4. Heat transfer
- 7.5. Civil engineering and architecture
- 7.6. Projectile weapons
- 7.7. Ocean engineering
- 7.8. Other aspects of mechanical engineering

Scientists and engineers from the German-speaking world also made numerous contributions to overlapping and related areas of engineering listed in Chapters 6 (electrical and electromagnetic engineering), 8 (nuclear engineering), and 9 (aerospace engineering).

7.1 Writing and Printing

German-speaking creators made many of the major innovations in technologies for writing and printing, including:[2]

- 7.1.1. The printing press
- 7.1.2. Typewriters
- 7.1.3. Stationery supplies
- 7.1.4. Improved printing processes

---

[2] For coverage of different aspects of this area, see especially: Ebeling 1985; Eisenstein 2005; Febvre and Martin 2010; Füssel 2004; Halkasch 1993; Hellbeck 2008; Kapr 1996; Kasischke 1999; Lassnig 1993; Lessing 2003, 2010; Michael Rauck 1983; Max Rößler 1982; Schlesinger 1989; Schmidt-Bachem 2011; Technisches Museum Wien 2005; Waize 2003; Wolf 1974.

7.1.1 Printing Press

Although this event preceded the time period that is the primary focus of this book, it would be impossible not to mention that Johannes Gutenberg (Mainz, ca. 1400–1468) invented the printing press around 1436 [Eisenstein 2005; Febvre and Martin 2010; Füssel 2004; Kapr 1996]. See Fig. 7.1. Donald Cardwell, a professor of the history of technology, described the enormous significance of Gutenberg's innovations [Cardwell 1995, p. 55]:

> Gutenberg's printing press revolutionized the publication of books. The first known printed book, produced at Mainz in 1455, was the Gutenberg Bible. It has been estimated that more books were published in the first fifty years following Gutenberg (up, that is, to the beginning of the sixteenth century) than had been produced in the previous thousand years. A twentyfold increase in productivity is highly impressive and it would not be unreasonable to regard Gutenberg as the first production engineer. Furthermore, it is easy to overlook Gutenberg's achievement of complete interchangeability in manufacture; each little unit of type could be used over and over again and fitted between any other little units[...] Finally, his invention brought about the first revolution in information technology. It was to be a long time—two hundred and fifty years—before another invention as dramatic and as important as Gutenberg's was to be made.

7.1.2 Typewriters

As shown in Fig. 7.2, Karl von Drais (German states, 1785–1851) created a paper music recorder in 1812 and then the first keyboard typewriter in 1821, [Ebeling 1985; Lessing 2003, 2010; Michael Rauck 1983]. He also invented the first bicycle (p. 1491).

In the English-speaking world, credit for producing the first practical typewriters has traditionally been assigned primarily to Christopher Latham Sholes (U.S., 1819–1890), Carlos Glidden (U.S., 1834–1877), and James Densmore (U.S., 1820–1889), who marketed what became known as Remington typewriters beginning in the 1870s.

In fact, the first practical typewriters were invented and demonstrated a decade earlier by Peter Mitterhofer (Austrian, 1822–1893). Building upon the earlier work by Karl von Drais, Mitterhofer produced his first model in 1864. Mitterhofer created a series of improved models in rapid succession after that until around 1869 [Lassnig 1993; Technisches Museum Wien 2005; Waize 2003]. See Fig. 7.3. Lutz Rolf, an historian of science at the Berlin Technical University, explained how innovative Mitterhofer's work was [Technisches Museum Wien 2005, pp. 108–110]:

> The basic concept of Mitterhofer's models thus builds on the idea that all functions of the machine can be controlled by the keyboard. Even the cylindrical paper carrier mechanism used in the later models, which cleverly automated line spacing and the return of the platen, subscribes to this concept. [...]

> Mitterhofer's overall aim was to replace handwriting with a mechanised process derived from printing. As new technical solutions needed to be developed and combined for a vast range of different functional elements, a stepwise approach was adopted. Mitterhofer built several different models to experiment with, which he kept adding to and improving on in order to achieve his overall aim. [...]
>
> His design incorporates features that other typewriters were only to offer much later and was the most advanced typewriter of its time. Even from today's vantage point, some of the solutions Mitterhofer came up with for individual problems can still be regarded as the best possible.
>
> Mitterhofer's work was decisively influenced by the fact that, apart from creative talent, he also possessed remarkable technical skill and experience as well as a talent for improvisation. In addition, he also built his models himself. He was thus able to put his ideas into practice and test them directly. This may also be why, despite the sheer scope of detail solutions required and the host of construction problems he encountered, it only took him six years to create his machine, from the initial idea to the production of the prototype. The development of Sholes and Glidden's design, by comparison, which was embarked on much later, involved a great number of engineers and technicians who needed more than a decade to produce a machine comparable to Mitterhofer's creation.

As it turns out, even the Sholes/Remington typewriters that appeared a decade later in the United States were designed and built by German mechanics (Fig. 7.4). Sholes, Densmore, Remington, and their fellow financial backers wanted a typewriter that they could mass-produce and sell. However, for the actual design, development, and construction of suitable typewriters, they hired a machine shop owned and staffed by German-speaking and German-trained mechanics who had immigrated to the United States, and run by Carl Friedrich Kleinsteuber (German, 1822–1885). Kleinsteuber appointed a team led by Mathias Schwalbach (German, 1834–1920), who ultimately had a long career designing and building many clever machines, such as very sophisticated sewing machines, clocks, and watches [https://oztypewriter.blogspot.com/2011/09/on-this-day-in-typewriter-history-cxxii.html]. Schwalbach, Kleinsteuber, and others on the team used their own mechanical knowledge, and presumably also designs such as Mitterhofer's coming out of Europe, in order to design their typewriters. They produced a prototype in 1872 and then a series of improved versions after that, which Sholes and Remington began selling in the mid-1870s. The U.S.-born sponsors claimed most of the public credit for the line of typewriters, whereas the German-born creators were largely forgotten.

7.1.3 Stationery Supplies

In 1844, Friedrich Gottlob Keller (German, 1816–1895) invented a wood-grinding machine for mass-producing paper (Fig. 7.5). Prior to that time, paper had been made from cloth rags, which were in short supply and therefore greatly limited the maximum production rate and minimum cost of paper. Machines based on Keller's design revolutionized the production of paper and quickly became used worldwide.

As shown in Fig. 7.6, the Hungarian brothers László Bíró (1899–1985) and György Bíró (18??–19??) developed the ballpoint pen during the period 1931–1938. The science historian Felix Paturi described their invention [Paturi 1998, p. 529]:

“Kuli” revolutioniert das Schreiben	“Pen” revolutionizes writing
Die ungarischen Brüder Ladislao und Georg Biró erfinden den Kugelschreiber.	The Hungarian brothers László and György Bíró invent the ballpoint pen.
Das Grundprinzip des neuen Schreibgeräts ist einfach: Ein länglicher, im Griff eingearbeiteter Behälter (Mine) ist mit Tinte gefüllt. An ihrem vorderen Ende läuft die Mine konisch zu und wird durch eine kleine Kugel abgedichtet, die sich in einer Lagerpfanne drehen kann. Führt man den Stift mit der Kugel über Papier, befördert sie durch Rotation etwas Tinte aus der Mine auf die Schreibfläche. Die technischen Schwierigkeiten liegen zunächst in der Entwicklung einer geeigneten zählflüssigen und schnell trocknenden Tinte. Nachdem die Biró-Brüder eine solche Schreibflüssigkeit entwickelt haben, ist der weltweite Siegeszug des “Kulis” nur noch eine Frage der Zeit.	The basic principle of the new writing instrument is simple: an elongated container (refill) incorporated into the handle is filled with ink. At its front end, the refill tapers and is sealed by a small ball that can rotate in a bearing cup. When the ball and pen are placed over paper, the ball rotates and transports some ink from the refill to the writing surface. The technical difficulties initially lie in the development of a suitable viscous and quick-drying ink. Now that the Bíró brothers have developed such a writing fluid, the worldwide triumphal march of the “Kulis” is only a matter of time.

Friedrich Soennecken (German, 1848–1919) invented the paper hole punch and ring binders for hole-punched papers in 1886 [Hellbeck 2008]. See Fig. 7.7.

7.1.4 Improved Printing Processes

Beginning in 1796, Alois Senefelder (Austrian/German states, 1771–1834) developed lithography for printing illustrations, as shown in Fig. 7.8. The *Encyclopedia Britannica* explained how Senefelder developed his invention [EB 2010]:

> German inventor of lithography. [...] Desiring to publish plays that he had written but unable to afford the expensive engraving of printing plates, Senefelder tried to engrave them himself. His work on copper plates was not proving very successful when an accident led to his discovery of the possibilities of stone (1796). Senefelder records that one day he jotted down a laundry list with grease pencil on a piece of Bavarian limestone. It occurred to him that if he etched away the rest of the surface, the markings would be left in relief. Two years of experimentation eventually led to the discovery of flat-surface printing (modern lithography).

After using single lithography plates to reproduce black-and-white illustrations in his early work, by 1818 Senefelder had developed methods to use multiple lithography plates with different colors of ink to make color illustrations [Bunch and Hellemans 2004, p. 306]. Very similar lithographic techniques of protecting and etching different parts of surfaces are now also widely used to make semiconductor devices (Section 6.5).

Friedrich König (German states, 1774–1833) and Andreas Bauer (German states, 1783–1860) developed the steam-powered printing press in 1814 [Halkasch 1993; Kasischke 1999; Max Rößler 1982; Wolf 1974]. See Fig. 7.9.

Paul Pretsch (German?, 18??–19??) and A. J. Berchtold (German?, 18??–19??) did early work and Georg Meisenbach (German, 1841–1912) perfected the halftone method for reproducing photographs with tiny printed dots [Dorothea Peters 2007]. Figure 7.10 shows the first image that Meisenbach produced with his final halftone method. This method is still widely used for newspapers, magazines, and computer printers.

As shown in Fig. 7.11, Ottmar Mergenthaler (German, 1854–1899) was born and educated in Germany, then emigrated to the United States. During the period 1876–1899, he developed linotype machines for rapid typesetting for printing presses [Schlesinger 1989]. Oxford University's *Biographical Dictionary of Scientists* described the mechanism and importance of Mergenthaler's invention [Porter 1994, p. 478]:

> Before Linotype, printing was carried out by hand-setting, a long and laborious process. Mergenthaler's invention speeded this operation and made printed matter, from books to penny news sheets, cheaper to produce. The design of the machine enabled a line of type (hence the name) to be composed at one time and cast as a single piece of metal. The machine was rather like a large typewriter, about 2 m/6½ ft high, with a store of matrices (moulds) at the top. The operator selected the letters by means of rods controlled by the 'typewriter' keys, and these letters fell through tiny trapdoors to drop into position in a line setting. As each line was completed it was passed on to the 'metal pot' area where a cast was made to form a 'slug' with the letters in relief on one side.

> This then fitted into a page of type ready for printing, while the matrices were returned to the store at the top of the machine for reuse.
>
> A person operating one of Mergenthaler's keyboards could set type up to three or four times faster than by hand-setting, cutting the labour cost of production to a fraction of before. The machine heralded a new age for printing in which books became affordable, and newspapers could really claim to carry up-to-the-minute information, for the Linotype made it possible to change and reset copy to within minutes of going to press.

The German-speaking world developed advanced methods of printing that were transferred to other countries after World War II. See Fig. 7.12 for just one example among many [NARA RG 40, Entry UD-75, Box 3, Folder Press Releases].

See also pp. 1013 and 1162 for German-speaking contributions to electronic technologies for document printing, document transfer, and document storage.

OFFICE OF TECHNICAL SERVICES

Bimetallic printing plates developed by the Germans, said to be good for more than a million impressions in printing bank notes, are described in a report now on sale by the Office of Technical Services, Department of Commerce.

The 59-page report, prepared by British printing industry experts for the British Intelligence Objectives Sub-Committee, describes the operation of 18 German printing and printing supply firms.

The bimetallic plates are made of brass with nickel-steel electro-deposited over the non-printing areas. Re-nickeling of the plate after a run of 800,000 is recommended. The plates are said to be economical in the use of ink and to make possible greater continuity in large printing runs. Speeds of 10,000 to 15,000 impressions an hour are claimed.

Other noteworthy developments described in the report are:

Recent advances in the "Eggen" and "Efha" processes for deep etching of lithographic plates.

Light plastic spacing furniture, made by injection molding, said to be in regular use for letter press printing.

Heat treatment of a cellulose varnish to produce a high finish on show cards.

Book binding techniques, including wire book sewing machines which are widely preferred to thread sewing in Germany.

Printing machines, producing up to 4 colors on one side with one color on the reverse and operating at speeds up to 3,000 sheets an hour.

"Aktophot" projection camera and other photocopying apparatus.

Manufacture of gravure inks with a water base.

Use of "Astrolon", a celluloid-like vinyl chloride sheet, for measuring scales, rulers and protractors, as well as bases for originals in photelithography and other photo reproduction work.

Klimsch "Stator" machine, claimed to be rapid and economical for applying an even emulsion coating to photosensitive plates.

A dry collodion process for 3 or 4 color separations.

"Unfortunately, this report gives little working detail on many points", commented Robert Reiss, chief of OTS' Technical Industrial Intelligence Division. "More intensive studies of the German printing industry are still possible, however. TIID can arrange for American experts to visit plants described in this report and other important industrial targets. Individuals and firms interested in sending investigators to Germany should communicate with OTS immediately."

Orders for the report (German Printing Industry; PB-34044; photostat, $4; microfilm, $2; 59 pages), should be addressed to the Office of Technical Services, Department of Commerce, Washington 25, D. C., and should be accompanied by check or money order payable to the Treasurer of the United States.

7.2 Musical Instruments

The quantity and quality of musical contributions by composers from the predominantly German-speaking central European world are well known. Composers such as those listed in Table 7.1 remain household names worldwide, even centuries later.

Name	**Nationality**	**Lived**
Johann Sebastian Bach	German states	1685–1750
Carl Philipp Emanuel Bach	German states	1714–1788
Johann Christian Bach	German states	1735–1782
Ludwig van Beethoven	German states	1770–1827
Alban Berg	Austrian	1885–1935
Johannes Brahms	German	1833–1897
Josef Anton Bruckner	Austrian	1824–1896
Fryderyk Chopin	Polish	1810–1849
Antonín Dvořák	Czech/Austrian	1841–1904
Christoph Willibald Gluck	German states/Austrian	1714–1787
Georg Friederich Handel	German states	1685–1759
Joseph Haydn	Austrian	1732–1809
Michael Haydn	Austrian	1737–1806
Paul Hindemith	German	1895–1963
Leoš Janáček	Czech/Austrian	1854–1928
Franz Liszt	Austro-Hungarian	1811–1886
Gustav Mahler	Austrian	1860–1911
Fanny Mendelssohn	German states	1805–1847
Felix Mendelssohn	German states	1809–1847
Leopold Mozart	Austrian	1719–1787
Wolfgang Amadeus Mozart	Austrian	1756–1791
Carl Orff	German	1895–1982
Johann Pachelbel	German states	1653–1706
Arnold Schoenberg	Austrian	1874–1951
Franz Schubert	Austrian	1797–1828
Robert Schumann	German states	1810–1856
Clara Schumann	German	1819–1896
Heinrich Schütz	German states	1585–1672
Bedřich Smetana	Czech/Austrian	1824–1884
Johann Strauss	Austrian	1825–1899
Richard Strauss	German	1864–1949
Georg Philipp Telemann	German states	1681–1767
Richard Wagner	German	1813–1883
Carl Maria von Weber	German states	1786–1826
Anton Webern	Austrian	1883–1945
Kurt Weill	German	1900–1950

Table 7.1: Examples of well-known musical composers from the predominantly German-speaking central European world.

While it is less well known to the general public, German-speaking creators also made enormous contributions to the development of modern musical instruments and equipment, including:[3]

7.2.1. Woodwind instruments

7.2.2. Brass instruments

7.2.3. Pianos

7.2.4. Metronomes

7.2.1 Woodwind Instruments

As shown in Fig. 7.13, Johann Christoph Denner (German states, 1655–1707) developed the clarinet around 1700. Iwan Müller (Baltic German, 1786–1854) later created airtight key pads for it and other woodwinds. Anthony Baines, an Oxford University musicologist and curator of musical instruments, praised Denner's creation [Baines 1991, p. 297]:

> The clarinet, Germany's great contribution to the woodwind, marks the first full exploitation in Western musical history—possibly in all history—of the upper register of a reed-sounded cylindrical tube. It was invented about the beginning of the eighteenth century by J. C. Denner of Nuremberg or his son. Doppelmeyr's 'Historical Report of Nuremberg Mathematicians and Craftsmen,' 1730, names the father.
>
> Denner was one of the leading German woodwind-makers of the end of the seventeenth century[...]

Although simple flutes had been used since antiquity, Theobald Böhm (German, 1794–1881, Fig. 7.14) developed the modern Western concert flute during the period 1831–1847. Anthony Baines explained some of the steps that Böhm went through to perfect his flute design [Baines 1991, pp. 320–322]:

> When Boehm returned to Munich, his keen, analytical mind faced up squarely to the question of the large holes, and he quickly decided to incorporate them on a systematic basis throughout the instrument. Moreover, he went yet a step further: he conceived the idea of securing *full venting* for the notes by changing all the existing closed keys into open keys—i.e. into keys standing normally open.
>
> This reversed key-system demanded some novel method of control, and for this Boehm embodied a mechanical device that had appeared already in rudimentary forms in the workshops of other experimental flute-makers: the now-familiar rings, through which a finger can operate a key in the same movement as closing its own hole. Thus he produced the *conical Boehm flute*, 1832, the greatest of all landmarks in the modern history of woodwind design. [...]
>
> Search for yet greater volume and freedom of sound led Boehm next to reason thus, assisted by experiments with numerous bits of brass tubing[...]

---

[3] Baines 1991, 1993; Ulrich Michels 2008; Sachs 1940; Wilkinson 2014.

> With this, Boehm had found his *cylindrical bore* (1847), the bore of the flute today. The holes, he discovered, should have at least three-quarters of the diameter of the bore, making covered action (finger-plates) necessary. Hole I was an exception to the rule: for the sake of the upper D's it had to be smaller than the other holes, and placed rather high up the flute. Boehm's first instruments were of silver, though late in life he himself changed to wood, or silver with wooden head.

The modern oboe (sometimes called the Wiener or Viennese oboe) was developed in stages by Johann Eichentopf (German states, 1678–1769), Jacob Denner (German states, 1681–1735), Stefan Koch (Austrian, 1772–1828), Karl Friedrich Golde (German, 1803–1873), Josef Hajek (Austrian, 1849–1926), and Hermann Zuleger (Austrian, 1885–1949). See Fig. 7.15.

The modern bassoon (sometimes called the Heckel bassoon) was developed by Gottfried Weber (German states, 1779–1839), improved by Carl Almenräder (German states, 1786–1846), and perfected by Johann Adam Heckel (German, 1812–1877), as illustrated in Fig. 7.16. Anthony Baines described the contributions of Almenräder and Heckel [Baines 1991, pp. 338–339]:

> The story of the Heckel bassoon begins about 1825, when Carl Almenraeder, a bandmaster and contemporary of the Savarys, set out to cure certain faults of the classical bassoon. [...]
>
> Thus far, Almenraeder was entirely successful, producing an instrument on which the notes came out as steadily and evenly as they do on the small woodwind. But the tone-quality suffered. [...] It has been the achievement of the firm of Heckel to undo the damage to the tone while yet preserving the technical benefits. The work included patient attention to the bore [...] and refinement of the manufacture by every possible means. During one period, Wagner himself was in and out of the workshop watching progress with keen interest.

The harmonica was created around 1821 in the German-speaking world and then copied so rapidly by several craftsmen there that it is unclear which one of them actually originated the instrument (Fig. 7.17). Proposed creators of the harmonica include Christian Friedrich Buschmann (German states, 1805–1864), Anton Häckl (Austrian, 17??–18??), Georg Anton Reinlein (Austrian, 1766–1834), and Joseph Richter (Austrian, 17??–18??).

In a very similar fashion, the accordion was developed around 1822 in the German-speaking world and immediately copied by craftsmen there. Proposed creators of the accordion include the same Christian Friedrich Buschmann, Cyrill Demian (Austrian, 1772–1849), and Carl Friedrich Uhlig (German, 1789–1874, inventor of the concertina). See Fig. 7.18. The *Encyclopedia Britannica* summarized some of what is known of the origins of the accordion [EB 2010]:

> The advent of the accordion is the subject of debate among researchers. Many credit C. Friedrich L. Buschmann, whose *Handäoline* was patented in Berlin in 1822, as the inventor of the accordion, while others give the distinction to Cyrill Demian of Vienna, who patented his *Accordion* in 1829, thus coining the name. A modification of the *Handäoline*, Demian's invention comprised a small manual bellows and five keys, although, as Demian noted in a description of the instrument, extra keys could be incorporated into the design. Numerous variations of the device soon followed.

7.2.2 Brass Instruments

Anton Joseph Hampel (Austrian/German states, 1710–1771) invented tuning slides for brass horns in 1753 or earlier. See Fig. 7.19.

Friedrich Blühmel (German states, 1777–1845) and/or Heinrich Stölzel (German states, 1777–1844) created valves for brass horns around 1813 (Fig. 7.19). Anthony Baines explained what is known of their history [Baines 1993, pp. 206–207]:

> In 1815 the *Allgemeine musikalische Zeitung* printed the historic communication from Breslau [...], signed by the director of the theatre there:
>
> NEW INVENTION
>
>> Kammermusikus Heinrich Stölzel of Pless in Upper Silesia has, for the perfection of the *Waldhorn*, devised a simple mechanism by which a chromatic scale of nearly three octaves, with all non-natural notes clear and strong, and similar in sound to the natural notes, is obtained by means of two levers for the right hand. [...]
>
> Heinrich Stoelzel (as he was sometimes more conveniently spelt) was then a thirty-eight year old horn-player in the orchestra of Prince von Pless. At once he began to advertise the new horn, performing on it at Leipzig in 1817[...] Next year he found himself a place in the royal orchestra at Berlin. He had, however, left out of the reckoning his younger collaborator, Friedrich Blühmel, a member of the miners' band (*Berg-Hoboist*) and for all we know a horn-player too. Blühmel chased to Berlin, to claim that the horn had been his and sold by him to Stoelzel. A ten-year Prussian patent was then issued in 1818 jointly to the two men ([...] both are described as coming from Waldenburg, today Walbrzych, southwest of Breslau, where Pless had a castle). [...] Stoelzel finally bought off Blühmel on the expiry of the patent. Both were evidently mechanics as well as musicians. But the only writer who knew them both personally, the great Berlin bandmaster Wilhelm Wieprecht, said that though the two men had worked together in Silesia for many years, their subsequent quarrels made it quite impossible to find out which of them had conceived the idea first.

Those two mechanical inventions—tuning slides and valves—revolutionized the entire family of brass musical instruments.

Wilhelm Friedrich Wieprecht (German, 1802–1872) and Johann Gottfried Moritz (German states, 1777–1840) invented the tuba in 1835. Moritz's son, Carl Wilhelm Moritz (German states, 1810–1855), created the tenor tuba in 1838. See Fig. 7.20. Anthony Baines wrote [Baines 1993, p. 250]:

> Still early in the period of these bombardons, Moritz and Wieprecht, in or just before 1835, produced their *Bass-tuba*. This very compact but rather heavy F bass has a valve bore of 15.5 mm. [...] Moritz's tuba won much admiration and must surely have been envisaged by Wagner in the opening of the *Faust* Overture, which no contemporary bombardon could have managed.

Edmund Gumpert (German, 18??–19??) and Friedrich Kruspe (German, 18??–19??) invented the modern double horn, sometimes called the "French" horn, in 1897, as illustrated in Fig. 7.21.

7.2.3 Pianos

Early pianos first evolved from harpsichords and clavichords, apparently in Italy, but then a series of German-speaking creators made numerous mechanical innovations to develop modern pianos (Fig. 7.22). Some of the major creators included Gottfried Silbermann (German states, 1683–1753), Christoph Gottlieb Schröter (German states, 1699–1782), Christian Ernst Friederici (German states, 1709–1780), Johann Christoph Zumpe (German states, 1726–1790), Johann Andreas Stein (German states, 1728–1792), and Johann Heinrich Pape (German states, 1789–1875). Musicologist Curt Sachs emphasized the dominance of German-speaking creators in the development of pianos [Sachs 1940, pp. 393–395]:

> Italy invented the piano, but then abandoned it. The Germans adopted the art and evolved and transformed the piano; for the following forty years pianos were made exclusively in Germany.
>
> The first and best early maker of grand pianos in Germany was the famous organ builder GOTTFRIED SILBERMANN, of Freiberg, Saxony. He was well acquainted with Johann Sebastian Bach, who criticized and advised him in his attempts, and Frederick the Great of Prussia bought three of the pianos which are now in Potsdam palaces. [...]
>
> This simple action was given an escapement about the year 1770, probably by JOHANN STEIN in Augsburg. In 1777, Wolfgang Amadeus Mozart wrote to his father that he had called on Stein's workshop. "His instruments distinguish themselves by an escapement; not one in a hundred makers troubles himself about that; but without an escapement a piano clatters and leaves a sound[...]" This action with an escaping hammer connected with the key was called first the *German action*, and later on, when the STEIN family had moved to Vienna, the *Viennese action*. [...]
>
> In 1760 a dozen Saxon piano makers, jobless on account of the Seven Years' War, came to settle in London. After this move Germany was no longer the exclusive piano-making country; England began to compete seriously and soon became the leading center. The most famous among the German makers in London were JACOB KIRCHMANN, who changed his name to KIRCKMAN, and JOHANN CHRISTIAN ZUMPE, a former pupil of Silbermann. [...] The first pianist, too, was a German on English soil—Johann Christian Bach, Johann Sebastian's youngest son, gave the world's first piano recital in 1768 in London.

7.2.4 Metronomes

Though technically not a musical instrument, metronomes are an extremely useful tool for musicians. In or before 1814, Dietrich Nikolaus Winkel (Lippstadt, 1777–1826) invented the metronome. Johann Mälzel (German states, 1772–1838) improved and mass-produced metronomes. See Fig. 7.23.

Gottfried Silbermann (1683–1753)

7.3 Internal Combustion Engines and Motor Vehicles

In the eighteenth and early nineteenth centuries, most of the major innovations regarding steam engines and vehicles employing them occurred in the United Kingdom and France [Ingo Müller 2007]. Yet when it came time to supersede steam technology with improved engines in the late nineteenth century, it was the more recently developed German-speaking scientific world that rose to the challenge. Indeed, during the late nineteenth and earlier twentieth centuries, engineers from the German-speaking world were responsible for virtually all of the key innovations in the development of internal combustion engines as well as vehicles and tools powered by them, including:[4]

7.3.1. Motorcycles, motorboats, automobiles, and trucks

7.3.2. Chainsaws

7.3.3. Military tanks

7.3.4. Diesel train locomotives

Those German designs were rapidly copied in the United States and other countries, while the German-speaking world soon entered the decades-long period of World Wars I and II and their respective aftermaths, which greatly hindered German and Austrian industries from competing globally in the very technologies that they had pioneered. As a result, most people in the modern world do not realize how directly all of these creations can be traced to German-speaking creators.

7.3.1 Internal Combustion Engines, Motorcycles, Motorboats, Automobiles, Trucks

Figure 7.24 shows early steps away from steam engines. ?? Brackenburg (German?, 18??–18??) developed an automobile powered by a hydrogen/oxygen combustion engine in 1836. Julius Hock (Austrian, 18??–19??) developed an oil-burning internal combustion engine in 1873 [Cummins 2002].

With assistance from Eugen Langen (German, 1833–1895), Nikolaus Otto (German, 1832–1891) developed the four-stroke internal-combustion gasoline engine in 1876 [Cummins 2002]. See Fig. 7.25. Gasoline automobile engines still go through the steps known as the Otto cycle. *1001 Inventions That Changed the World* explained the importance of Otto's innovations, as well as his connections to later German engine designers [Challoner 2009, p. 400]:

> German engineer Nikolaus Otto (1832–1891) was responsible for one of the great developments in motorized vehicles with the invention of his four-stroke cycle internal combustion engine.

---

[4] For coverage of different aspects of this area, see especially: Cummins 2002; Graf and Metternich 1986; Ludvigsen 2015; Popplow 2011; Raidt 2014; Roth and Schmid 1987; Technisches Museum Wien 2006; Völker 2013.

> After developing an interest in technology, he began designs for a four-stroke engine based on Lenoir's earlier design for a two-stroke cycle. In 1864 he set up N. A. Otto and Cie alongside Eugen Langen, creating the world's first engine manufacturers. In 1872, he employed Gottlieb Daimler and Wilhelm Maybach as technical director and chief designer, respectively.
>
> In 1876 the first practical four-stroke engine was constructed. The four strokes are an intake stroke, where the piston moves down to allow a fuel-air mixture into the combustion chamber, a compression stroke, where the piston moves back up to compress the gases, a combustion or power stroke, where a spark ignites the fuel and the piston is forced down again, and a final exhaust stroke, where the piston moves up to expel spent fuel via the exhaust valve. [...]
>
> Initially combustion engines were stationary as they could not be adapted to run on liquid fuel and so required a pilot light. Otto solved this problem in 1884 with the invention of a magneto ignition system that created the spark needed for the power stroke. This increased the practicality of the four-stroke engine and allowed it to be used by Daimler and Maybach in the first motorcycles and automobiles.

As illustrated in Fig. 7.26, Wilhelm Wittig (German?, 18??–19??) and Wilhelm Hees (German?, 18??–19??) developed a two-stroke internal-combustion engine in 1878 [Cummins 2002].

Emile Capitaine (German, 1861–1907) developed an oil-burning internal combustion engine in 1879, a series of gasoline engines in the 1880s–1890s, and a motorcycle in 1896 [Cummins 2002]. See Fig. 7.27.

Rudolf Diesel (German, 1858–1913), shown in Fig. 7.28, created the first Diesel engines in the 1890s [Cummins 2002]. Diesel engines are also internal combustion engines but go through a series of steps somewhat different than the standard Otto cycle. *Encyclopedia Britannica* described the process by which Diesel developed his invention [EB 2010]:

> Diesel devoted much of his time to the self-imposed task of developing an internal combustion engine that would approach the theoretical efficiency of the Carnot cycle. For a time he experimented with an expansion engine using ammonia. About 1890, in which year he moved to a new post with the Linde firm in Berlin, he conceived the idea for the diesel engine. He obtained a German development patent in 1892 and the following year published a description of his engine under the title *Theorie und Konstruktion eines rationellen Wärmemotors* (*Theory and Construction of a Rational Heat Motor*). With support from the Maschinenfabrik Augsburg and the Krupp firms, he produced a series of increasingly successful models, culminating in his demonstration in 1897 of a 25-horsepower, four-stroke, single vertical cylinder compression engine. The high efficiency of Diesel's engine, together with its comparative simplicity of design, made it an immediate commercial success, and royalty fees brought great wealth to its inventor.

Siegfried Marcus (German/Austrian, 1831–1898) developed an internal-combustion-engine-powered car in 1870, and then a greatly improved version in 1888 [Technisches Museum Wien 2006]. Figure 7.29 presents photos of Marcus and his two car versions.

As shown in Fig. 7.30, Karl Benz (German, 1844–1929) and his wife Bertha Benz (German, 1849–1944) developed and demonstrated an internal-combustion-engine-powered automobile in 1885 [Cummins 2002]. *1001 Inventions That Changed the World* explained how they publicized their first automobile [Challoner 2009, p. 446]:

> Benz recognized the great potential of petrol as a fuel. His three-wheeled car had a top speed of just ten miles (16 km) per hour with its four-stroke, one-cylinder engine. After receiving his patent in January 1886, he began selling the Benz [...], but the public doubted its reliability. Benz's wife Bertha had a brilliant idea to advertise the new car. In 1888 she took it on a 60-mile (100 km) trip from Mannheim to near Stuttgart.

Benz developed other automobiles such as the first mass-produced automobile (Velo) in 1894, the first internal-combustion-engine-powered bus (Omnibus) in 1895, and a record-setting race car (Blitzen) in 1909 [Grünewald and Williamson 2013; Roth and Schmid 1987]. See Fig. 7.31.

Gottlieb Daimler (German, 1834–1900) and Wilhelm Maybach (German, 1846–1929), shown in Fig. 7.32, initially worked for Nikolaus Otto but then started their own company. They created the first internal-combustion-powered motorcycle (Reitwagen) in 1885 and their first internal-combustion-powered automobile (Motorcoach) in 1886 [Cummins 2002; Raidt 2014; Völker 2013]. Daimler and Maybach also created the first internal-combustion-powered boat in 1886 and the first internal-combustion-powered truck in 1896; see Fig. 7.33. Oxford University's *Biographical Dictionary of Scientists* described the key to their success [Porter 1994, p. 159]:

> The genius of Daimler and Maybach lay in the combining of four of the elements essential to the modern car engine: the four-stroke Otto cycle, the vaporization of the fuel with a device similar to a carburettor, low weight and high speeds. Lenoir had used electric ignition, but this proved unreliable; Daimler and Maybach used an igniter tube that was light, worked well and operated independently of engine speed.

As illustrated in Figs. 7.34–7.36, in 1900, Wilhelm Maybach, Paul Daimler (German, 1869–1945), and Emil Jellinek (German/Austrian, 1853–1918) radically rethought the look of "horseless carriages" and developed the first automobile with a recognizably modern design, the Mercedes 35 hp. This was the first of a long line of automobiles that were named after Jellinek's daughter, Mercédès Jellinek (Austrian, 1889–1929) [Roth and Schmid 1987]. In the United States, Henry Ford's first Model T automobile, produced in 1909, was essentially a carbon copy of that 1900 German design. Soon thereafter, the German-speaking world was plunged into decades of war and the aftermath, giving great advantage to such foreign-made copies in the global market.

Robert Bosch (German, 1861–1942) created a magnetic engine ignition system and spark plugs in 1887 [Raidt 2014]. He was later joined by Gottlob Honold (German, 1876–1923), with whom he developed improved automobile engines, the car horn, and automotive headlights. See Fig. 7.37.

Figure 7.37: Robert Bosch created a magnetic engine ignition system and spark plugs in 1887. He was later joined by Gottlob Honold, with whom he developed improved automobile engines, the car horn, and automotive headlights.

Figure 7.38 presents several other automotive creators:

- Paul Winand (German?, 18??–19??) also developed spark plugs in 1887 [Cummins 2002].
- Donát Bánki (Hungarian, 1859–1922) and János Csonka (Hungarian, 1852–1939) produced an improved carburetor.
- Hugo Mayer (German?, 18??-19??) created hydraulic auto brakes.
- Wilhelm von Opel (German, 1871–1948) introduced assembly line production of automobiles in Europe.
- Ludwig Elsbett (German, 1913–2003) developed improved diesel engines, as well as engines that run on vegetable oil as biofuel [www.elsbett-museum.de].

As shown in Fig. 7.39, Edmund Rumpler (Austrian, 1872–1940) not only was the first aircraft manufacturer in Germany, but also designed aerodynamic automobiles (such as the 1923 Rumpler-Benz Tropfenwagen), created a unified engine and gearbox, and developed swing-axle rear suspension [Graf and Metternich 1986].

Ferdinand Porsche (Austrian/German, 1875–1951) created the first gasoline-electric hybrid automobile (Lohner-Porsche) in 1900; see Fig. 7.40. In fact, development, production, and use of electric vehicles continued to be emphasized in the German-speaking world through 1945. For example, BIOS 384, *German Battery Electric Vehicles and the German Storage Battery Industry*, p. 28, reported:

> The GERMANS make very much more use of battery electric vehicles of all forms than is the custom in BRITAIN. They also employ batteries, both lead-acid and nickel-iron for a greater range of uses.

As shown in Fig. 7.36, Porsche also did early design work at Daimler, such as for the 1924 Mercedes 15/70/100 PS and its successors (later named the Mercedes-Benz Type 400).

For his later projects, Porsche was joined by Karl Rabe (Austrian, 1895–1968). Porsche, Rabe, and their team developed the prototype for what would become the Volkswagen Beetle (1931, Fig. 7.41), as well as a series of Auto Union racing cars in the 1930s [Christopher 2013, pp. 199–203; Ludvigsen 2015].

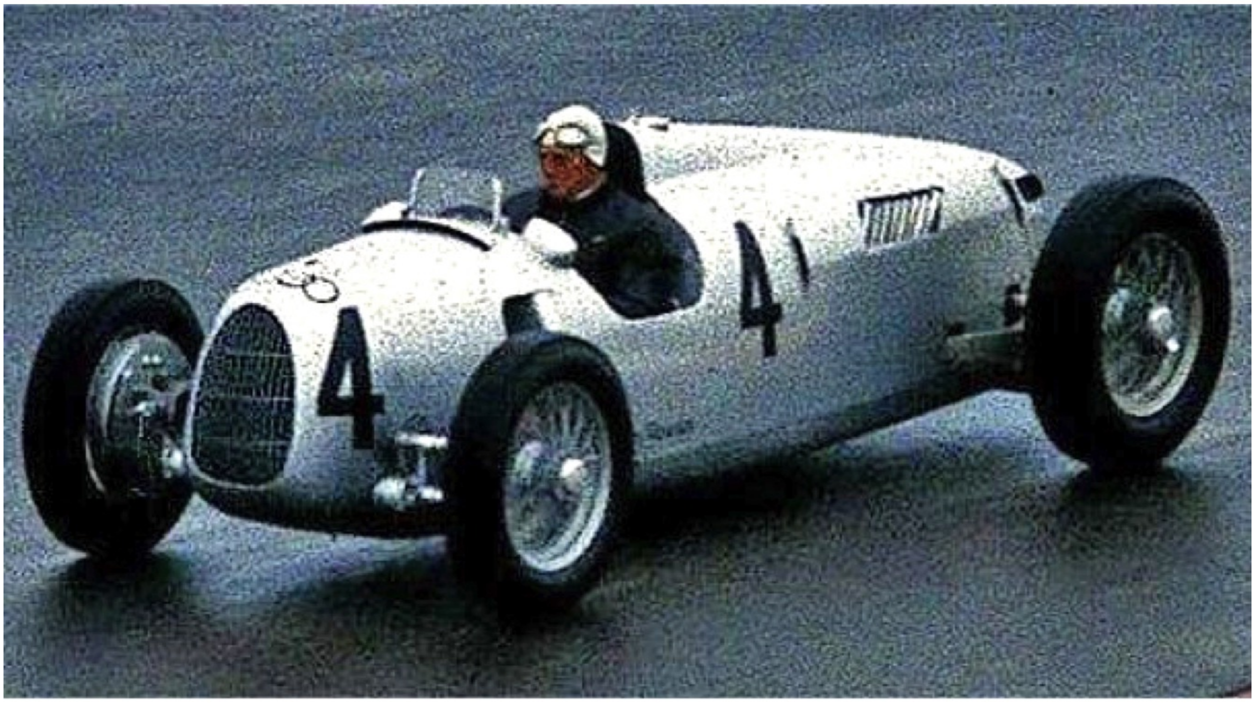
Porsche prototype for what would become the Volkswagen Beetle (1931)



Porsche Auto Union racing cars (1933–1939)

Figure 7.41: Ferdinand Porsche, Karl Rabe, and their team developed the prototype for what would become the Volkswagen Beetle (1931), as well as a series of Auto Union racing cars in the 1930s.

Oxford University's *Biographical Dictionary of Scientists* described some of Porsche's innovations [Porter 1994, pp. 560–561]:

> In 1936, he received a contract from the German government to develop the Volkswagen and plan the factory where it would be built. Just before this he conceived a racing car, without contract. The project was taken over by Auto Union and the car subsequently claimed victories on virtually every race track in Europe between 1934 and 1937, as well as many class records.
>
> The first VW prototypes were on the road by the end of 1935[...] Some other design jobs, however, had appeared alongside the major Volkswagen contract to cause Porsche to expand his company. [...H]e led the development of light tractors. Those tractors built to Porsche licence and under the firm's supervision after World War II can be traced to these designs. Concepts were also developed by him for aviation engines as well as plans and designs or wind-driven power plants—large wind-mills with automatic sail adjustment which delivered electric current via generators.
>
> The war cut short further development of the Volkswagen so Porsche designed the Leopard and Tiger tanks used by German Panzer regiments and helped to develop the V-1 flying bomb. [...]
>
> Porsche was a brilliant engineer whose genius reached into many disciplines. It has been said that the torsion-bar suspension alone would have sufficed to establish a monument to his name in the automotive industry. He can be considered one of the pioneers of aircooled engines in the industry.

Karl Schlör (German, 1911–1997), shown in Fig. 7.42, designed the Schlörwagen highly aerodynamic automobile in 1936 and demonstrated it in 1939 [Christopher 2013, pp. 199–201]. Even on today's roads, the Schlörwagen would look very forward-thinking.

German-speaking engineers not only took automobiles every step of the way from their first invention to high-speed aerodynamic models; they also carried motorcycles from their first creation (p. 1344) to sleek racing models. For example, when fitted with an aerodynamic shell, the BMW 500 Kompressor motorcycle model held the worldwide speed record for motorcycles from 1935 to 1951 (Fig. 7.43). It had a top speed of 279.5 km/hr in 1937.

As illustrated in Fig. 7.44, Felix Wankel (German, 1902–1988) developed Wankel rotary engines from 1924 onward. Hanns Paschke (German, 19??–??) later developed additional versions of Wankel engines [Popplow 2011]. Due to their very compact size, Wankel engines have been used in motorcycles, small cars, and small aircraft.

In addition to the transfer of engine and automotive technologies out of the German-speaking world that occurred in the late nineteenth and early twentieth centuries, Allied countries removed an enormous amount of information on more advanced engine and automotive technologies at the end of World War II. The United States, United Kingdom, France, and Soviet Union removed engineers, prototypes, patents and other documents, and even whole factories. They also wrote detailed reports about the German and Austrian technologies that were transferred to Allied industries. For a few examples, see Figs. 7.45–7.47. There are a large number of additional examples among the BIOS ER, BIOS, BIOS Misc., BIOS Overall, CIOS ER, CIOS, FIAT, *FIAT Review*, JIOA, NavTecMisEu LR, and NavTecMisEu reports in the Bibliography.

Many other automotive-related technologies were also developed in the German-speaking world and then transferred to other countries. Examples include:

- Synthetic rubber for tires (p. 656).
- Synthetic oil for engine lubrication (p. 720).
- High-temperature metal alloys for engines with higher fuel efficiencies (p. 689).
- High-temperature ceramics for engine components (p. 667).
- Improved battery technologies (p. 615).
- Piezoelectric and photoelectric sensors inside engines to monitor engine performance in real time [e.g., pp. 1129–1130 and FIAT 575, *Developments in Diesel Engineering*].
- Fuel additives to prevent knocking in engines [e.g., BIOS 1612, *Fundamental Work on Combustion in Germany*].
- Nitrous oxide for short-term boosting of engines [e.g., BIOS 1612, *Fundamental Work on Combustion in Germany*].

As shown in Fig. 7.48, Walter Linderer (German, 19??–19??) filed the first patent on an automotive airbag in 1951. During World War II, a great deal of German research was focused on developing rapidly deployable vehicle safety devices such as ejection seats, parachutes, and chemically heated/inflatable clothing for water landings (Section 9.4). Moreover, many patent applications filed in the early years of the postwar West German patent office were based on wartime work. Therefore, it seems likely that Linderer's airbag patent was based on wartime projects. More archival research is needed to investigate the origins of Linderer's invention.

In order to make a truly practical airbag, it was necessary to develop a system that could fully inflate the airbag within less than 0.1 seconds during a collision. Working for Daimler-Benz, Helmut Patzelt (German?, 19??–??), Gerhard Schiesterl (German?, 19??–??), and Albert Seybold (German?, 19??–??) solved that problem. They developed an airbag deployed by a solid propellant gas generator in 1967, and they patented the system in 1971 (Fig. 7.49).

The solid propellant gas generator was essentially a miniature solid propellant rocket that used the exhaust gas to inflate the airbag. That aspect of the invention drew heavily upon the earlier development of solid explosives (Section 3.4) and solid propellant rockets (Section 9.8) in the German-speaking world.

German-designed airbag technology was rapidly copied and adopted by Japanese and American automobile manufacturers.

OFFICE OF THE PUBLICATION BOARD

German-built diesel engines have more power in relation to their weight than American-made diesels, according to a U. S. Army Transportation Corps report now on sale by the Office of the Publication Board, Department of Commerce. However, American engines last considerably longer than German ones.

The Army's preliminary comparison of a popular, slow-speed, long-life, high-powered American diesel engine with a German diesel of similar size and application revealed that the German engine could produce 25 percent more power at approximately 31 percent less engine speed, with the same ratio of pounds to horsepower and within approximately the same space requirements.

The standard light-weight German diesel has more than twice as much horsepower per cylinder as the largest, high-speed, light-weight diesel engine made in America, though the German engine is built on the four-cycle, and the American one on the two-cycle principle, according to the report. In pounds per horsepower, the German engine is 22 percent lighter than the American engine. The ratio of horsepower to space occupied is about the same for the two engines.

The Army's studies reveal that the Germans had made far-reaching advances in the diesel field before and during both world wars. Several years in advance, they began to prepare for military demands by developing high performance engines. Under the Hitler regime, engine manufactures were heavily subsidized by the Government, and available technical skill was funneled into their research laboratories and experimental plants.

Some of these German developments, made at a probable sacrifice of progress in the commercial field, may not prove to be economically adaptable by America's peacetime industry. In order to save as much weight as possible, the Germans adopted many features which might be considered too costly by American standards, since they require a larger number of parts and more man-hours.

Other developments may help to advance the American industry. "With the unparalleled capacity of our engineers to produce complex machinery in mass production, it appears highly desirable to investigate the basic technical developments of the German designers, with the view of making these advancements practical for mass production and thereby economical for military as well as commercial application," the report states.

- 2 -

In addition to three charts comparing American and German diesel engines, the report contains numerous diagrams of German diesels.

Orders for the report (PB-1710; photostat, $2; microfilm, 50 cents; 18 pages) should be addressed to the Office of the Publication Board, Department of Commerce, Washington 25, D. C., and should be accompanied by check or money order, payable to the Treasurer of the United States.

OFFICE OF TECHNICAL SERVICES

Plans for a 2-cylinder, 25-horsepower, air-cooled diesel engine for the German light automobile, "Volkswagon," are described in a report now on sale by the Office of Technical Services, Department of Commerce. The diesel unit was intended to be interchangeable with the gasoline engines used in the "Volkswagen" but not a single engine was ever built, according to the report.

The report was prepared by a joint American-British investigating team in May, 1945, for the combined Intelligence Objectives Sub-Committee. One section of the report, which may be purchased separately, describes the diesel engine for the "Volkswagen." However, most of the report is devoted to the research activities in tank construction at the Porsche plants in Stuttgart and Fallersleben.

The Porsche firm, named after a noted German engineer, originally developed the "Volkswagen" or "people's car." Shortage of gasoline was the incentive for development of the new replacement unit for the "Volkswagen." Designs were completed by May, 1945.

Plans for the new engine, which was to have two cylinders horizontally opposed, called for the following specifications: a 3.346-inch bore; 3.937-inch stroke; 34.63 cubic inch cylinder capacity; 1:17.5 compression ratio; 24.7 horsepower maximum output at 2400 rotations per minute; and 2000 rotations per minute continuous speed with 21.7 horsepower output. The weight of the diesel unit was to be about 221 pounds, 38 pounds more than the weight of the gasoline engine. The use of compression ignition and air cooling in a 25-horsepower engine of this type are novel features, according to the report.

Complete specification data on the engine, including drawings, are contained in the report.

The remainder of the report deals chiefly with German developments in tank designs, particularly the "Maus" tank, weighing 185 British tons. One section contains data, including photographs, of a light tractor designed to operate on gas produced from burning wood chips.

The report contains charts and diagrams pertaining to the equipment discussed. Some of the drawings will not reproduce well.

Orders for the complete report (Wartime Activities of Dr. Porsche, K.G.; PB-23024; photostat, $29; microfilm, $4.50; 435 pages) should be addressed to the Office of Technical Services, Department of Commerce, Washington, 25, D. C., and should be accompanied by check or money order, payable to the Treasurer of the United States.

Those desiring only that section of the report which deals with the new "Volkswagon" engine should order Report PB-36282 (Two-Cycle Air-Cooled Engine for Volkswagen; photostat, $4, microfilm, $2).

OTS-502

Advance Release For
Monday, December 2, 1946

OFFICE OF TECHNICAL SERVICES

A complete German laboratory for Diesel engine research has been received by the Office of Technical Services, Department of Commerce, John C. Green, Director, announced today. Weighing 68 tons and shipped from Germany in 70 crates, the equipment when assembled will comprise one of the most modern diesel engine research laboratories yet constructed in the United States.

Diesel engineers who have investigated the German industry for OTS have been unanimous in the opinion that American technicians can learn much from German developments, Mr. Green explained. The laboratory will facilitate their work.

The machines, tools, and instruments concerned were taken from the Klockner-Humboldt-Deutsch factory, at Oberusel, Germany, near Stuttgart. They include diesel engines from one to sixteen cylinders, numerous pulsators, centrifugal test stands, heat treating furnaces, units of industrial X-ray equipment, impact and hardness testing machines, dynamometers, instrument panels, and other testing devices and accessories.

After consultation with representatives of the automotive industry, the U. S. Office of Education, and educational institutions, the laboratory will be set up at a suitable technical school. It is possible, Mr. Green said, that by supplementing the German equipment with other equipment already available, two laboratories may be assembled.

The Diesel laboratory project has been sponsored by the Automotive Advisory Committee, consisting of representatives of American automotive firms working in cooperation with OTS. Howard C. Dickinson, formerly chief of the Heat and Power Division, National Bureau of Standards, is chairman of the Committee. Dr. Dickinson is also past president and honorary life member of the Society of Automotive Engineers. Lloyd R. Worden, Chief of the Aeronautics and Automotive Unit of OTS' Technical Industrial Intelligence Division, is secretary. Other members are B. B. Bachman, vice-president, Autocar Co., Ardmore, Pa; A. T. Colwell, vice-president, Thompson Products Inc., Cleveland, Ohio; A. W. Herrington, chairman, Marmon-Herrington, Inc., Indianapolis, Ind; W. S. James, Ford Motor Co., Dearborn, Mich; Otis D. Treiber, technical consultant, Hercules Motor Co., Canton, Ohio; Austin M. Wolf, director of standards, Division of Standards and Purchases, State of New York, New York City.

Einrichtung zum Schutze von in Fahrzeugen befindlichen Personen gegen Verletzungen bei Zusammenstößen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 6. Oktober 1951 an
Patentanmeldung bekanntgemacht am 26. Februar 1953
Patenterteilung bekanntgemacht am 1. Oktober 1953

Bei Zusammenstößen von Kraftwagen entstehen die meisten Verletzungen dadurch, daß die Insassen nach vorn geschleudert werden und dabei gegen harte Gegenstände stoßen, an denen sie sich Verletzungen zuziehen. Um derartige Verletzungen zu vermeiden, sind schon verschiedene Vorrichtungen vorgeschlagen worden, die jedoch meist teuer in der Herstellung und kompliziert sowie nicht immer sicher in der Funktion sind.

Demgegenüber bezieht sich die Erfindung auf eine sehr einfache Einrichtung, deren Funktionsfähigkeit die Insassen des Fahrzeuges jederzeit überprüfen können und die die Bequemlichkeit des Fahrzeuges nicht einschränkt. Gemäß der Erfindung wird vor dem Sitz der zu schützenden Person ein aufblasbarer Behälter in zusammengefaltetem Zustand montiert, der sich im Fall der Gefahr automatisch oder durch willkürliche Auslösung aufbläht, so daß die betreffende Person bei einem Zusammenstoß gegen diesen weichen, elastischen Behälter geschleudert wird, wo sie keine Verletzungen erleidet.

In der Zeichnung ist ein Ausführungsbeispiel der Erfindung schematisch dargestellt und nachstehend beschrieben, ohne daß die Erfindung jedoch auf diese Ausführungsform beschränkt sein soll.

Fig. 1 zeigt die Einzelheiten der Vorrichtung und
Fig. 2 den im Fall der Gefahr aufgeblähten Behälter im Innern eines Kraftwagens.

Vor dem Sitzplatz der Insassen bei einem Kraftwagen, also zweckmäßig für die Vordersitze am Armaturenbrett oder an der Decke des Wagens, für die Rücksitze an der Rückseite der Vordersitze, befindet sich ein zusammenlegbarer elastischer und möglichst wenig luftdurchlässiger Behälter 1, der durch ein Ventil 2 mit einem Preßluftbehälter 3 in Verbindung steht. Als Preßluftquelle kann eine Preßluftflasche dienen oder auch ein Hohlgefäß, das mit einer anderweitig gelagerten Preßluftflasche oder einem Kompressor durch eine Leitung 4 verbunden ist. Ein zweckmäßig am Armaturenbrett befestigtes Manometer zeigt über die Leitung 5 den im Raum 3 herrschenden Luftdruck an, so daß

7.3.2 Chainsaws

German-speaking creators also invented chainsaws and adapted internal combustion engines to power them (Fig. 7.50).

Sometime before 1830, Bernhard Heine (German, 1800–1846) invented hand-powered chainsaws (osteotomes) for cutting bone during surgery, and then in 1830 he successfully promoted their use all over Europe. Heine was a surgeon who also made important discoveries about bone growth and bone repair. He likely would have made even more contributions during his career, but unfortunately he died from tuberculosis (probably acquired from his work).

In the late 1920s, Andreas Stihl (Swiss, educated and worked in Germany, 1896–1973), a mechanical engineer, developed both electric and gasoline-powered chainsaws. Based on his inventions, he founded the company that still bears his name.

At the same time, Emil Lerp (German, 1886–1966) also developed gasoline-powered chainsaws and founded the Dolmar company to produce them. Early in their careers, Lerp and Stihl worked together for the Emil Ring saw company, so it is somewhat murky whether one of them borrowed the ideas of the other, or if they developed their chainsaws truly independently.

Chainsaw designs were spread worldwide both by the Stihl and Dolmar companies and by Allied investigators at the end of World War II [see for example FIAT 696, *Gasoline Powered Hand Tree Saws*].

HAUPTPATENT

Andreas STIHL, Stuttgart (Deutschland).

Elektrische Handkettensäge.

Die Erfindung bezieht sich auf Kettensägen, welche mittelst eines Elektromotors angetrieben werden.

Gemäß der Erfindung ist der Motor und das erforderliche Zwischengetriebe über dem Kettenrad angeordnet.

Die Erfindung ist an einem Ausführungsbeispiel anhand der Zeichnung nachstehend beschrieben.

Fig. 1 zeigt eine gekürzte Seitenansicht der Handsäge,

Fig. 2 eine Draufsicht,

Fig. 3 eine Rückansicht,

Fig. 4 einen Querschnitt nach der Linie IV—IV der Fig. 1.

Die Handsäge weist einen Motor *a* auf, an dessen Gehäuse die Lagerdeckel *c* und *b* angeflanscht sind. Der Lagerdeckel *c* trägt zugleich das Lagergehäuse *d* für das Getriebe, bei welchem zum Beispiel die Motorwelle *e* über eine Zwischenwelle *f* das Kettenrad *g* über die Schiene *i*, welche zur Führung der Sägekette *h* dient, verlegt und daher eine gleichmäßige Verteilung des Gewichtes und auch ein gleichmäßigerer Schnitt erzielt werden kann. Das Kettenrad *g* treibt in bekannter Weise eine mit Zähnen versehene Sägekette *h*, welche über die Schiene *i* geführt ist und am dem Kettenrad *g* gegenüberliegenden Ende der Schiene über ein Wenderad g^1 läuft. Die Schiene *i* ist an einem seitlichen Arm *k* des Motorgehäuses *a* angebracht, der zugleich eine Lagerstelle für die Welle des Kettenrades *g* aufweist. Um eine sichere Führung der Kette *h* beim Schnitt und einen geraden Schnitt zu erhalten, ist die Schiene *i* an ihrer Unter- und Oberseite je mit einer Führungsrille *l* versehen, in welcher die Kette *h* mit ihrer nichtschneidenden Innenseite läuft. Zum Tragen der Säge dient einerseits ein Gabelgriff *m*, dessen beide seitlichen Schenkel an den Lagerdeckeln *b*

BREVET D'INVENTION.

Gr. 5. — Cl. 4. N° 676.716

Scie à chaîne sans fin pour l'abatage des arbres.

M. Emil LERP résidant en Allemagne.

Demandé le 14 juin 1929, à 14^h 50^m, à Paris.

Délivré le 29 novembre 1929. — Publié le 26 février 1930.

(Demande de brevet déposée en Allemagne le 14 juin 1928. — Déclaration du déposant.)

La scie à chaîne sans fin pour abattre les arbres, faisant l'objet de la présente invention, se distingue par la possibilité de transport et de montage spécialement simples. Elle repose de préférence sur trois pieds fixés sur des tiges, tubes, etc... verticalement déplaçables susceptibles d'être calés à hauteur voulue par un dispositif d'arrêt et pouvant être abaissés par simple pression exercée sur leurs extrémités supérieures. La scie comprend en outre deux paires de poignées se faisant face, aménagées de telle sorte sur la machine qu'elle puisse être transportée comme une civière et que les tiges de réglage des pieds se trouvent à proximité des porteurs. Ceux-ci sont donc à même après avoir lâché l'une ou

machine comme une brouette. La culasse de commande de la scie à chaîne sans fin est en général assujettie d'une manière élastique avec le rail de guidage de la scie afin que ce dernier puisse se mouvoir dans le sens de la hauteur, et ce dans un but qui sera exposé plus loin.

Au dessin annexé, donné à titre d'exemple, une forme d'exécution de la scie a été représentée, et à ce dessin :

Fig. 1 est une vue de face partielle de la machine, en la regardant du côté de la culasse de commande et du rail de guidage de la scie sans fin et ce dans une position de la culasse dans laquelle la scie et son guide travaillent dans un plan horizontal ;

Fig. 2 est une coupe partielle par la culasse

Figure 7.50: Bernhard Heine invented hand-powered chainsaws in 1830, Andreas Stihl developed electric and gasoline-powered chainsaws in the late 1920s, and Emil Lerp developed gasoline-powered chainsaws in the late 1920s.

7.3.3 Tanks

German-speaking creators were responsible for most of the major innovations in the development of military tanks powered by internal combustion engines or gas turbine engines.

As shown in Fig. 7.51, Frederick Simms (German, 1863–1944) developed the small armed Motor Scout in 1899, followed by the much larger Motor War Car in 1902. Then in 1904, Paul Daimler (German, 1869–1945) and his team developed the Panzerwagen armored car, pictured in Fig. 7.52.

In or before 1911, Günther Burstyn (Austrian, 1879–1945) invented the first combat tank to incorporate all of the major features of modern tanks (including treads, full armor, a large lower motor section, a smaller rotating turret with a long gun barrel of large caliber, and armored ports for smaller guns), as illustrated in Figs. 7.53–7.55. He tried unsuccessfully to interest many countries in funding him to mass-produce his combat tank, along the way publicizing his tank plans via presentations, patents (e.g., Fig. 7.54), and articles (e.g., Fig. 7.55). For example, he published a 1912 article that summarized the main features of his tank designs and included many accompanying diagrams [Burstyn 1912]:

> Die Bewegung im Gelände, besonders auf weichem Boden, erfolgt mit einem Paar über kleine breite Räder geführter endloser Bänder aus Drahtseilgeflecht. Diese Bänder fassen mit Rippen in den Boden ein und werden durch die äußeren, hochgestellten Räder, in welche sie zahnradartig eingreifen, angetrieben. Durch die Hochstellung dieser Räder sind die Bänder vorne und rückwärts schräg aufwärtsgeführt, so daß kleine Unebenheiten leicht überwunden werden können. Wendungen geschehen in der Weise, daß ein Band nach vorne, das andere nach rückwärts zum Antrieb gelangt. Im allgemeinen ist es das alte Prinzip der sich selbst Geleise legenden Lokomotive, das in letzter Zeit in ähnlicher Weise für Motorschlitten der antarktischen Expeditionen mit Erfolg angewendet wird.

> Movement in the terrain, especially on soft ground, is accomplished by a pair of endless belts made of braided wire rope guided over small wide wheels. These belts engage the ground with ribs and are driven by the outer raised wheels in which they mesh like cogwheels. Because of the raised position of these wheels, the belts are slanted upward at the front and back, so that small bumps can be easily overcome. Turns are executed in such a way that one belt is driven to move forward and the other backward. In general, it is the old principle of a locomotive laying tracks for itself, which has recently been successfully used in a similar way for snowmobiles on Antarctic expeditions.

> Zur Überschreitung von Hindernissen sind vorne und rückwärts an dem Fahrzeuge je zwei breite Gleitschienen, die an den äußeren Enden breite kleine Räder tragen, auslegerartig angebracht. Diese Gleitschienen sind um ihren Befestigungpunkt am Fahrzeuge im vertikalen Sinne schwenkbar und werden durch je eine Strebe gestützt. Die Schwenkung der Gleitschienen erfolgt durch die Streben, welche durch ein Getriebe, das vom Motor betätigt wird, entsprechend bewegt werden. Die Figuren 5–10 [Fig. 7.55] machen ersichtlich, wie das Motorgeschütz mit Hilfe der Gleitschienen eine Stufe überschreitet.

> In order to cross obstacles, two wide slide rails are attached to the front and two to the rear of the vehicle in the form of outriggers, which carry wide small wheels at the outer ends. These slide rails can be pivoted vertically about their point of attachment to the vehicle and are each supported by a strut. The pivoting of the slide rails is effected by the struts, which are moved accordingly by a gear operated by the motor. Figures 5–10 [Fig. 7.55] show how the motorized gun crosses a step with the aid of the slide rails.

Mit Hilfe der beschriebenen Fortbewegungsmittel erscheint die freie Bewegung des Motorgeschützes im Gelände gewährleistet. Hiebei sind zwei Geschwindigkeitsstufen erforderlich: eine normale (5–8 km pro Stunde) für das Fahren über freies Feld und eine langsame (zirka 3 km pro Stunde) für das Übersetzen von Hindernissen.

Zur raschen Bewegung auf Straßen, zu der die bisher beschriebene Art der Fortbewegung ungeeignet ist, sind zwei Paare von Rädern vorgesehen. Sie befinden sich unter dem Panzer und sind zum Heben, bzw. Senken eingerichtet. Die vorderen Räder beim Geschütz werden gelenkt, die rückwärtigen angetrieben. Die Geschwindigkeit, die auf Straßen erzielt werden soll, wird je nach der Motorstärke 20–30 km pro Stunde betragen.

Der Aufbau des Motorgeschützes ist so eingerichtet, daß sich vorne der Kampfraum, rückwärts der Motorraum befindet.

Der erstere wird oben durch eine drehbare Panzerhaube gebildet, die mit der Lafettierung des Geschützes in Verbindung steht. Auf dieses wird später näher eingegangen werden. Ferners befinden sich im Kampfraume für die zwei Mann Geschützbedienung Sitze, welche sich bei der Drehung der Haube mitbewegen.

Im Motorraum ist ein 40–60 H.P. Benzinmotor (Last wagentype) installiert. Ferners befindet sich dort der Sitz für den Motorwärter. Beiderseits von diesem sind geräumige Kästen zur Aufnahme von Benzin, Öl, Munition und Requisiten vorgesehen. Während des Feuergefechtes läßt sich der Motor- mit dem Kampfraum verbinden, so daß der Motorwärter die Zureichung der Munition besorgen kann.

With the help of the described means of locomotion, the free movement of the motor gun in terrain appears to be ensured. Two speed levels are required: a normal one (5–8 km per hour) for driving over open fields and a slow one (about 3 km per hour) for crossing obstacles.

For rapid movement on roads, for which the mode of locomotion described so far is unsuitable, two pairs of wheels are provided. They are located under the tank and are designed to be lifted or lowered. The front wheels on the gun are steered and the rear wheels are powered. The speed to be achieved on roads will be 20–30 km per hour, depending on the engine power.

The superstructure of the motorized gun is arranged so the fighting compartment is in the front and the engine compartment in the rear.

The former is formed at the top by a rotatable armored turret, which is connected to the mount of the gun. This will be discussed in more detail later. Furthermore, there are seats in the fighting compartment for the two-man gun crew, which move along with the rotation of the turret.

A 40–60 H.P. gasoline engine (truck type) is installed in the engine compartment. There is also a seat for the engine attendant. On either side of this are spacious boxes for storing gasoline, oil, ammunition, and props. During the firefight, the engine compartment can be connected to the fighting compartment, so that the engine attendant can resupply the ammunition.

Der Panzerschutz, welcher gleichzeitig den tragenden Rahmen für das Fahrzeug bildet, besteht aus Spezialstahl und ist vorne mit 8 mm, seit- und rückwärts mit 4 mm, an der Decke mit 3 mm Stärke angenommen. Die Panzerung nach unten gegen Geller wird wahrscheinlich auch notwendig werden.	The armor protection, which also forms the supporting frame for the vehicle, is made of special steel and is assumed to be 8 mm thick at the front, 4 mm thick at the sides and rear, and 3 mm thick on top. Underside armor against piercing will probably also be necessary.
Das Motorgeschütz, das infolge dieses Panzerschutzes gegen Infanteriefeuer fast unverwundbar erscheint, muß natürlich in der feind lichen Artillerie seinen stärksten Gegner erblicken und befähigt sein, den Kampf mit diesem zu bestehen.	The motorized gun, which as a result of this armor protection appears almost invulnerable to infantry fire, will of course find its strongest opponent to be enemy artillery and must be capable of holding its own against it.

Note that in addition to all of the now-common features of tanks, Burstyn's designs included two other novel options: retractable wheels underneath to allow faster travel on paved roads, and extendable wheeled beams on the front and back to aid in crossing over trenches.

Even though Burstyn was never able to find enough funding to fully develop his tanks himself, by widely publicizing his approach and designs through his international presentations, patents, and publications, it appears that he directly influenced engineers in several countries to implement his tank ideas for themselves during World War I.

Joseph Vollmer (German, 1871–1955) developed the first internal-combustion-engine-powered tractor-trailer truck in 1903; see Fig. 7.56. During World War I, he built upon the ideas of Günther Burstyn to create tanks such as the A7V.

As shown in Fig. 7.57, during World War II, Ferdinand Porsche, Karl Rabe, and their team developed advanced tanks such as the widely used Tiger I. They also created the huge 188-ton Panzerkampfwagen VIII Maus prototype [Ludvigsen 2015].

Another large tank prototype, the 140-ton Henschel Panzerkampfwagen E-100, was taken by British troops at the end of World War II. It is shown in Fig. 7.58 on top of a trailer, without the turret and treads.

Nicholas Straussler (Hungarian, 1891–1966), an automotive engineer, emigrated to the United Kingdom in the late 1920s due to rising intolerance in central Europe. From 1940 to 1944, he developed the duplex drive (DD) amphibious tanks that were used by Allied forces for the invasion of Normandy (Fig. 7.59).

German-speaking creators and their creations continued to influence tank design after World War II. In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed a number of important German innovations for tanks that were of interest to Allied countries [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 68–69]:

Investigation of the German automotive industry revealed that development was concentrated on armored fighting vehicles to the exclusion of ordinary motor transport. A new series of super heavy tanks, a group of self-propelled weapons knowns as "Waffentraeger", another series of tanks designated as the "E-Series" and the application of gas turbines as tank power plants were of particular interest.

The pilot model of the E-100 tank was located, and drawings of the important assemblies were evacuated by investigators. This tank weighed approximately 100 metric tons, mounted a 150 mm. gun and was provided with a sloping front armor plate 8 inches thick. It was discovered that an even heavier tank know as the "Maus" had been constructed and tested. The pilot model of this tank, which was reported to weigh 180 metric tons, was destroyed in the Russian area prior to occupation. [The Maus prototype was actually captured by the Russians—see Fig. 7.57.] However, complete engineering data on the "Maus" was obtained by CIOS investigators.

German authorities were planning mass production of self-propelled "Waffentraeger" guns. These gun mounts were lightly armored vehicles, which were to be equipped with normal field artillery weapons. It was initially conceived that provisions would be made for demounting the weapons for employment as conventional artillery pieces, but this feature was subsequently abandoned.

The "E-Series" of German tanks were the most interesting armored vehicles encountered. This series included the E-10, E-25, E-50 and E-100, all of which incorporated the most advanced thinking of the Heereswaffenamt. The series numbers represent the estimated weights of the basic chassis. It is significant to note that these vehicles represented a return of the German design trend to lighter and more maneuverable tanks.

The development of a gas turbine for tank motive power was not complete, nor had successful application been achieved. However, many US and British authorities believe that the gas turbine development is potentially the most important feature of German armored vehicle research. It was expected that a 30% increase in power would be obtained from substitution of a gas turbine for a conventional type power unit in a given size engine compartment. Considerable progress had been made on the development of a rotary ceramic heat exchanger capable of achieving fuel economy equal to that of the automotive type Diesel.

Tank armament projects included the rigidly mounted 75 and 88 mm. guns described previously. The design of gyroscopically stabilized sights led German experts to hope for an accuracy within a half-mile limit. The "Kugelblitz" anti-aircraft armored turret was discovered.

In respect to tank engines, designers had endeavored to produce an air-cooled Diesel power plant. The only successful new project encountered was the "Maybach HL-234" gasoline injection engine which had delivered 900 H.P. in preliminary tests.

The Germans had initiated many new projects of a more or less radical nature in the design of new tank transmissions. Electric drive had been tried but with little success. Turbo or torque converter-drive was considered the most promising of high horse-power applications.

BIOS 98, *Report on German Development of Gas Turbines for Armoured Fighting Vehicles*, pp. 3 and 13–14, gave more information on wartime development of gas turbine engines for tanks:

> During the investigation of the activities of Dr. Ing. Porsche, it was learned that he was associated with a project for the development of a gas turbine installation for the Tiger tank. The investigation was stated to be in the hands of Dipl. Ing. Otto Zadnik[...]
>
> The investigation of this target may be summed up briefly as follows:
>
> (a) Otto Zadnik was actually engaged upon the design of only one portion of the tank project, viz, the transmission. Although he had an over-riding responsibility for, and good general knowledge of the whole project, he was unable to provide details of the power unit.
>
> (b) Dr. Alfred Müller, who for some eighteen months, had been primarily responsible for turbine and turbo-blower development for aircraft (See his charter in Appendix 2) was made responsible for the design and development of the tank power unit. Dr. Müller has behind him a wide experience of gas turbines and blower development, but little or no development work appears to have been carried out on the tank motor itself. [...]
>
> (d) The torque characteristics (Scheme II), freedom from vibration, and the absence of any cooling system, make the gas turbine very attractive for tank use. [...]

During the war, Anselm Franz (Austrian, 1900–1994) developed gas turbine engines for jet fighters (Fig. 9.76). After the war, he came to the United States, where he brought the wartime dream of a gas turbine tank engine to reality. No later than 1951, he proposed the AGT1500 turboshaft engine to power U.S. tanks. After lengthy delays obtaining government funding, Franz finally demonstrated the AGT1500 engine in 1966. As shown in Fig. 7.60, the AGT1500 is still used in the M1A1 Abrams tank. Both in Germany during the war and in the United States after the war, Franz collaborated very closely with Heinrich Adenstedt (German, 1910–1991, pp. 697–698), an expert on high-temperature metal alloys.

KAIS. KÖNIGL. PATENTAMT.

Österreichische

PATENTSCHRIFT Nr 53248.

GUNTER BURSTYN in KORNEUBURG.

Vorrichtung für Motorfahrzeuge zum Überschreiten von Hindernissen.

Angemeldet am 1. März 1911. — Beginn der Patentdauer: 1. Jänner 1912.

Die Erfindung betrifft eine Vorrichtung, welche für Motorfahrzeuge bestimmt ist, um mit diesen Hindernisse im Terrain, wie Gräben, Stufen, Eisenbahndämme, zu überschreiten.

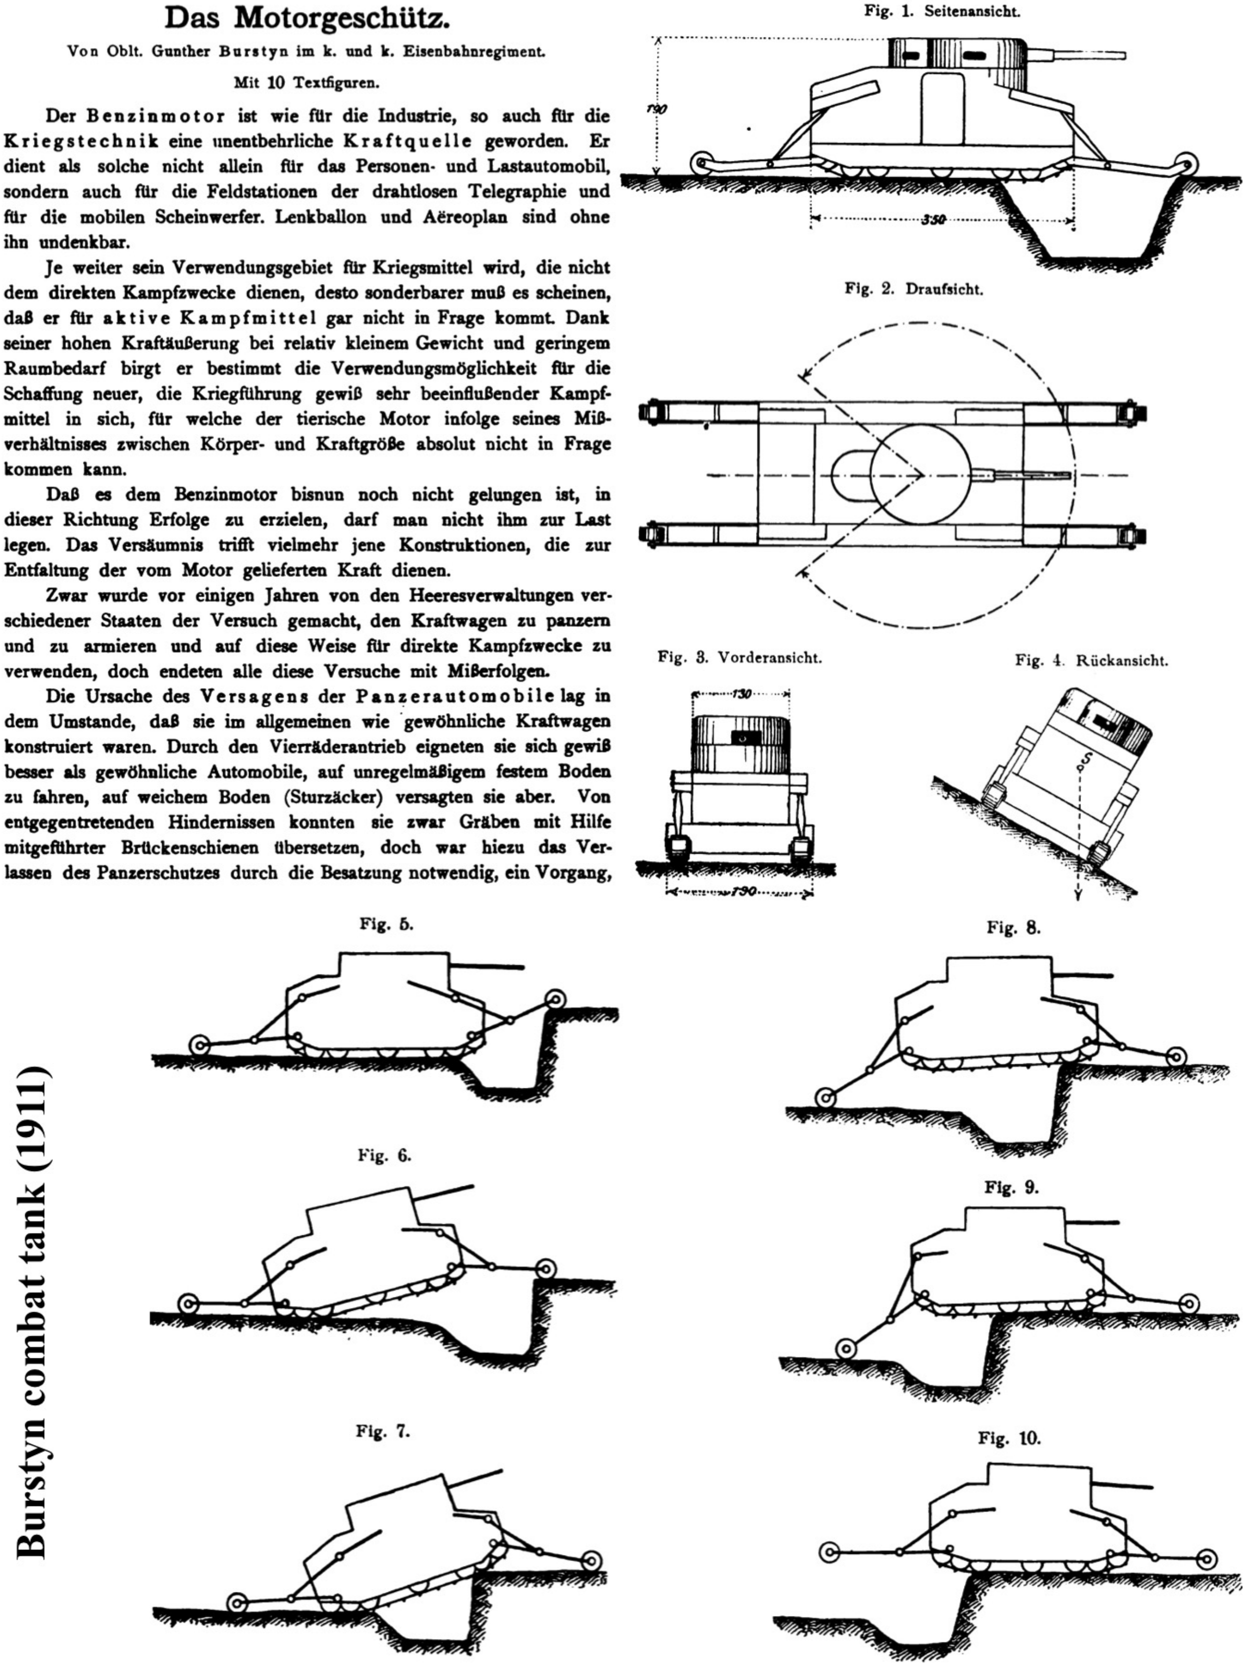
Die Fig. 1 und 2 zeigen die Vorrichtung für ein Motorgeschütz verwendet. Vorne und rückwärts am Fahrzeug sind je ein Paar Gleitschienen *u*, welche an den äußeren Enden kleine breite Räder *r* tragen, auslegerartig angebracht. Diese Gleitschienen sind um die Achsen *R* in vertikalem Sinne schwenkbar. Diese Bewegung erfolgt durch die die Gleitschienen stützenden Streben *a*. Das untere Ende der Streben ist in den Gleitschienen drehbar befestigt, das obere Ende zu einem Kreuzkopf *c* ausgestaltet. Dieser Kreuzkopf gleitet in den Führungen *f*; an ihm ist die fortschreitende, jedoch nicht drehbare Spindel *b* befestigt. Das Kegelrad *d* sitzt als Mutter auf der Spindel *b*. Der Antrieb des Kegelrades *d* erfolgt über das Kegelrad *e* vom Motor aus. Wird der Antrieb eingeschaltet, so dreht sich das Kegelrad *d* und bewegt als Mutter der Spindel *b* diese vor- bzw. rückwärts. Hiedurch wird der Kreuzkopf *c* ebenfalls nach vor- bzw. rückwärts bewegt, die Strebe *a* wird vorgedrückt bzw. angezogen und auf diese Weise das äußere Ende der Gleitschienen heruntergedrückt bzw. gehoben.

Die Fig. 3, 4, 5 und 6 zeigen die Verwendung der beschriebenen Konstruktion an einem Motorgeschütz angebracht. Und zwar ist in Fig. 3 das Übersetzen eines Grabens, in den Fig. 4, 5 und 6 das Überschreiten einer Terrainstufe dargestellt.

PATENT-ANSPRUCH:

Vorrichtung zur Übersetzung von Terrainhindernissen, insbesondere für gepanzerte, mit Geschützen armierte Motorfahrzeuge, gekennzeichnet durch am Vorder- und Hinterwagen des Fahrzeuges der Höhe nach schwenkbar angebrachte Gleitschienen *(u)*, die an ihren über das Fahrzeug hinausreichenden Enden mit Rädern versehen sind und vom Innern des Fahrzeuges aus entsprechend den zu überwindenden Hindernissen des Geländes einstellbar sind.

Figure 7.54: In or before 1911, Günther Burstyn invented the first combat tank to incorporate all of the major features of modern tanks. It also had extendable wheeled beams on the front and back to aid in crossing over trenches.



Das Motorgeschütz.

Von Oblt. Gunther Burstyn im k. und k. Eisenbahnregiment.

Mit 10 Textfiguren.

Der **Benzinmotor** ist wie für die Industrie, so auch für die **Kriegstechnik** eine unentbehrliche **Kraftquelle** geworden. Er dient als solche nicht allein für das Personen- und Lastautomobil, sondern auch für die Feldstationen der drahtlosen Telegraphie und für die mobilen Scheinwerfer. Lenkballon und Aëreoplan sind ohne ihn undenkbar.

Je weiter sein Verwendungsgebiet für Kriegsmittel wird, die nicht dem direkten Kampfzwecke dienen, desto sonderbarer muß es scheinen, daß er für **aktive Kampfmittel** gar nicht in Frage kommt. Dank seiner hohen Kraftäußerung bei relativ kleinem Gewicht und geringem Raumbedarf birgt er bestimmt die Verwendungsmöglichkeit für die Schaffung neuer, die Kriegführung gewiß sehr beeinflußender Kampfmittel in sich, für welche der tierische Motor infolge seines Mißverhältnisses zwischen Körper- und Kraftgröße absolut nicht in Frage kommen kann.

Daß es dem Benzinmotor bisnun noch nicht gelungen ist, in dieser Richtung Erfolge zu erzielen, darf man nicht ihm zur Last legen. Das Versäumnis trifft vielmehr jene Konstruktionen, die zur Entfaltung der vom Motor gelieferten Kraft dienen.

Zwar wurde vor einigen Jahren von den Heeresverwaltungen verschiedener Staaten der Versuch gemacht, den Kraftwagen zu panzern und zu armieren und auf diese Weise für direkte Kampfzwecke zu verwenden, doch endeten alle diese Versuche mit Mißerfolgen.

Die Ursache des **Versagens** der **Panzerautomobile** lag in dem Umstande, daß sie im allgemeinen wie gewöhnliche Kraftwagen konstruiert waren. Durch den Vierräderantrieb eigneten sie sich gewiß besser als gewöhnliche Automobile, auf unregelmäßigem festem Boden zu fahren, auf weichem Boden (Sturzäcker) versagten sie aber. Von entgegentretenden Hindernissen konnten sie zwar Gräben mit Hilfe mitgeführter Brückenschienen übersetzen, doch war hiezu das Verlassen des Panzerschutzes durch die Besatzung notwendig, ein Vorgang,

Figure 7.55: In or before 1911, Günther Burstyn invented the first combat tank to incorporate all of the major features of modern tanks. It also had extendable wheeled beams on the front and back to aid in crossing over trenches [Burstyn 1912].

7.3.4 Diesel Train Locomotives

German-speaking creators were responsible for adapting Diesel internal combustion engines to locomotives, where they continue to be used worldwide.

In 1912, Rudolf Diesel (German, 1858–1913) and Adolf Klose (German, 1844–1923) developed the first Diesel locomotive, shown in Fig. 7.61. The shaft of a Diesel engine rotates at high speeds and produces relatively small amounts of torque or force, yet a locomotive's wheels must rotate at relatively low speeds and apply large amounts of torque. Therefore, Diesel and Klose had to build an elaborate gear system to convert the high-speed, low-torque rotation of the engine shaft to low-speed, high-torque rotation of the wheels.

As illustrated in Fig. 7.62, in 1914 Hermann Lemp (Swiss, 1862–1954) developed the Diesel-electric drive for trains. Lemp's design used the Diesel engine to power an electric generator, then used that electricity to run electric motors connected to the wheels. Lemp's approach eliminated the need for a complex gearing system, since the electric generator could receive high-speed, low-torque power from the Diesel engine and produce electricity to power low-speed, high-torque electric motors attached to the wheels. In other words, the electric generator essentially took the place of the earlier gearing system. From 1920 onward, Lemp designed a number of Diesel-electric locomotives for the General Electric company in the United States. Diesel-electric locomotives rapidly replaced pure Diesel locomotives and any remaining steam locomotives, and they continue to dominate train systems around the world.

Werner von Siemens (German, 1816–1892) built the first electric train in 1879 and filed a patent application on electric trains in 1884 [Bähr 2016; von Siemens 1895]. See Fig. 6.3. His company built electric trains and systems for cities in Europe and North America.

Alfred Zehden (German, 1876–19??) invented magnetic levitation (maglev) trains in 1902 (p. 3204). Hermann Kemper (German, 1892–1977) patented improved maglev train systems in 1934 (p. 3213). From currently available documentation, it is not clear how far Zehden and Kemper got with actually building and testing maglev train systems, but their designs and principles have guided that technology ever since.

7.4 Heat Transfer

Heat, or thermal energy, may be transferred from one place to another by several different mechanisms. As illustrated in Fig. 7.63, those mechanisms include:

(a) Conduction

(b) Forced convection

(c) Natural convection

(d) Condensation and evaporation

(e) Boiling

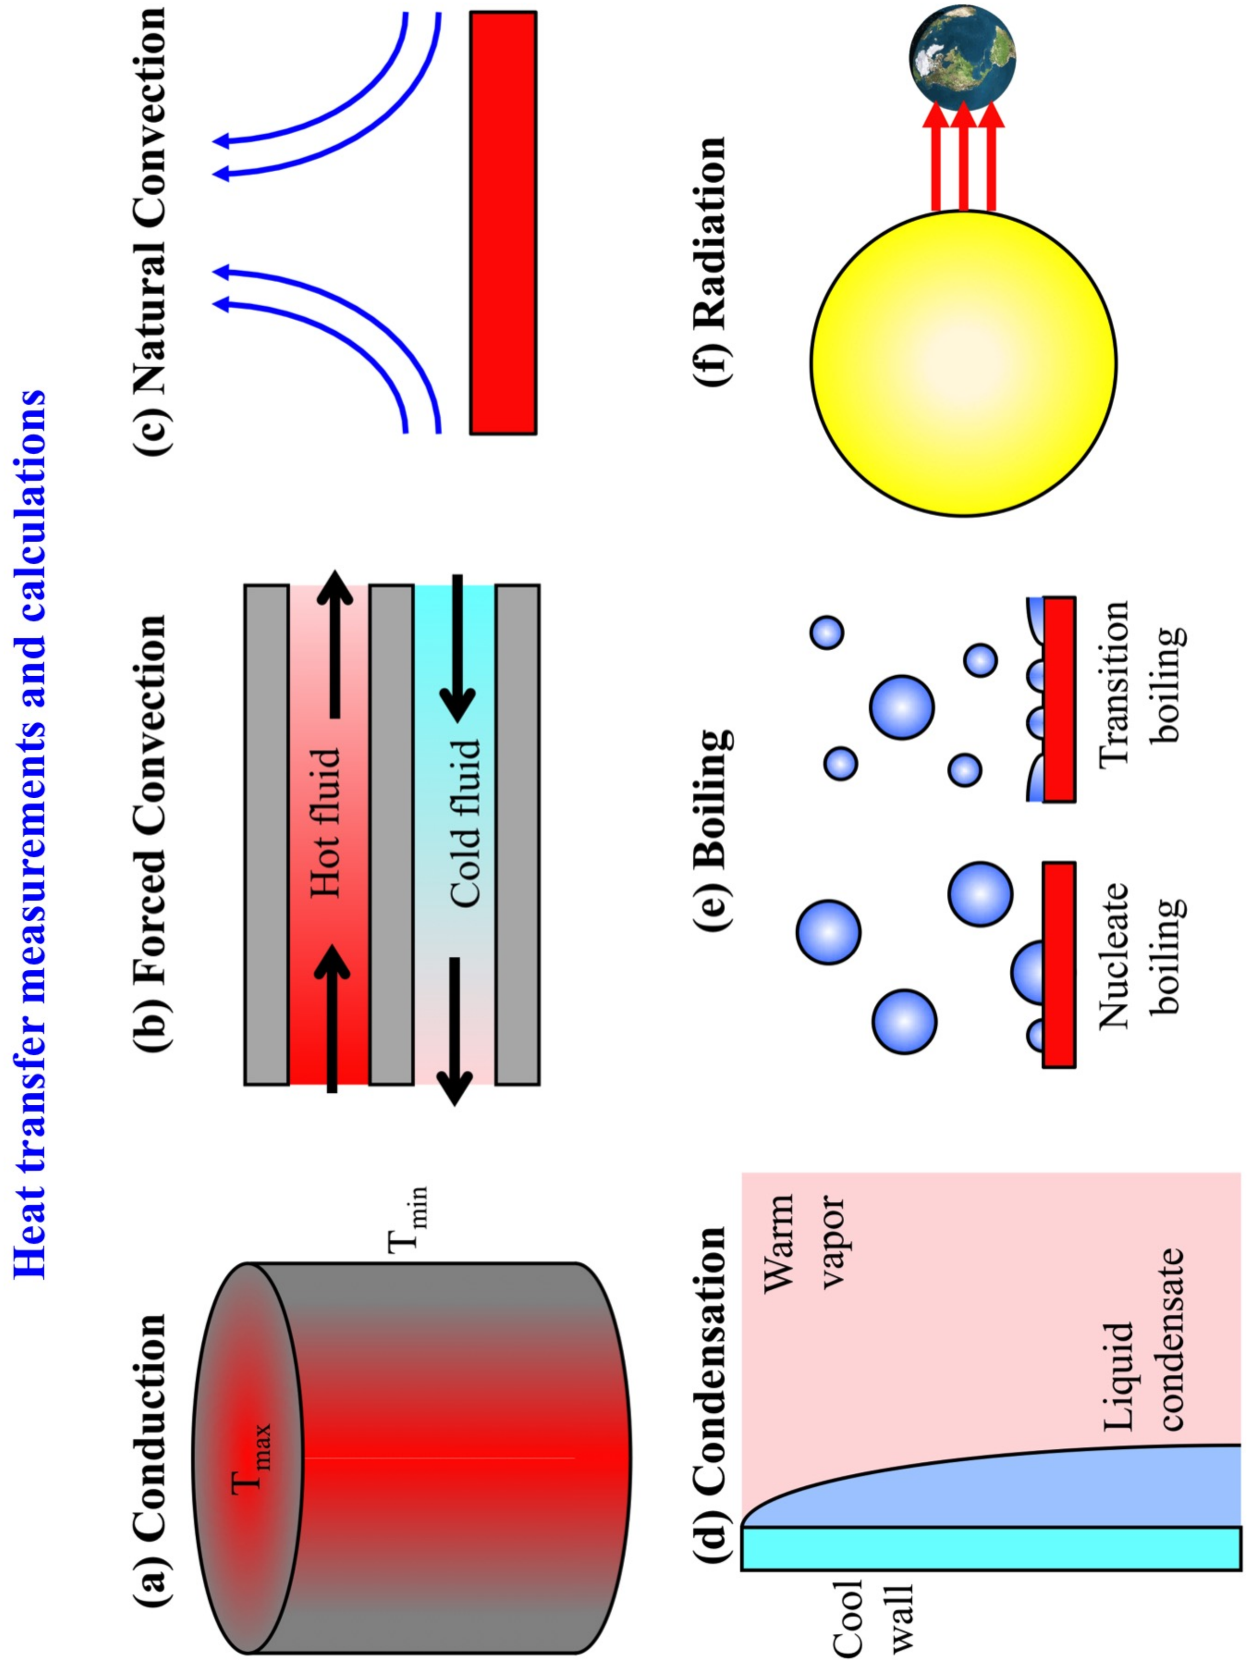
(f) Thermal radiation

For each type of heat transfer, the rate at which thermal energy is transferred depends in fairly complex ways on several different factors, such as the temperature difference, the composition of the materials involved, the surface area, and other variables. In general, heat transfer rates were first measured in a wide range of situations, and then the principles of physics were used to derive suitable equations to explain, extend, and generalize those empirical results. Those equations often involved "dimensionless numbers," or ratios of several parameters such that the measured dimensions cancel out, leaving only a number whose size governs the rate of heat transfer.

Once the heat transfer mechanisms were properly understood, they exploited to design cooling fins, heat exchangers, and other systems to control and utilize heat transfer. Heat transfer technology has enabled countless applications in the modern world, such as: thermal energy transport in heat engines and refrigerators; cooling of integrated circuit chips, nuclear reactors, and engines; and insulation of everything from thermos bottles to buildings.

Some of the earliest mathematical analyses of heat transfer were conducted by French scientists such as Jean Baptiste Biot (1774–1862) and Joseph Fourier (French, 1768–1830), although they had few successors, probably due to the long-term political turmoil in France. Some British scientists such as Osborne Reynolds (English, 1842–1912) and Thomas Edward Stanton (English, 1865–1931) also made relevant discoveries, yet their numbers were kept small by the relatively limited and focused British support for scientific research.

In contrast, the German-speaking world made a large number of contributions to heat transfer, due to its large-scale, long-term support for research in closely related fields such as internal combustion engines, aircraft engines, rocket engines, nuclear energy, aerodynamics, and other areas. Just a few illustrative examples of German-speaking scientists who carried out measurements and calculations of different modes of heat transfer are shown in Fig. 7.64 and discussed below.



Heat transfer measurements and calculations

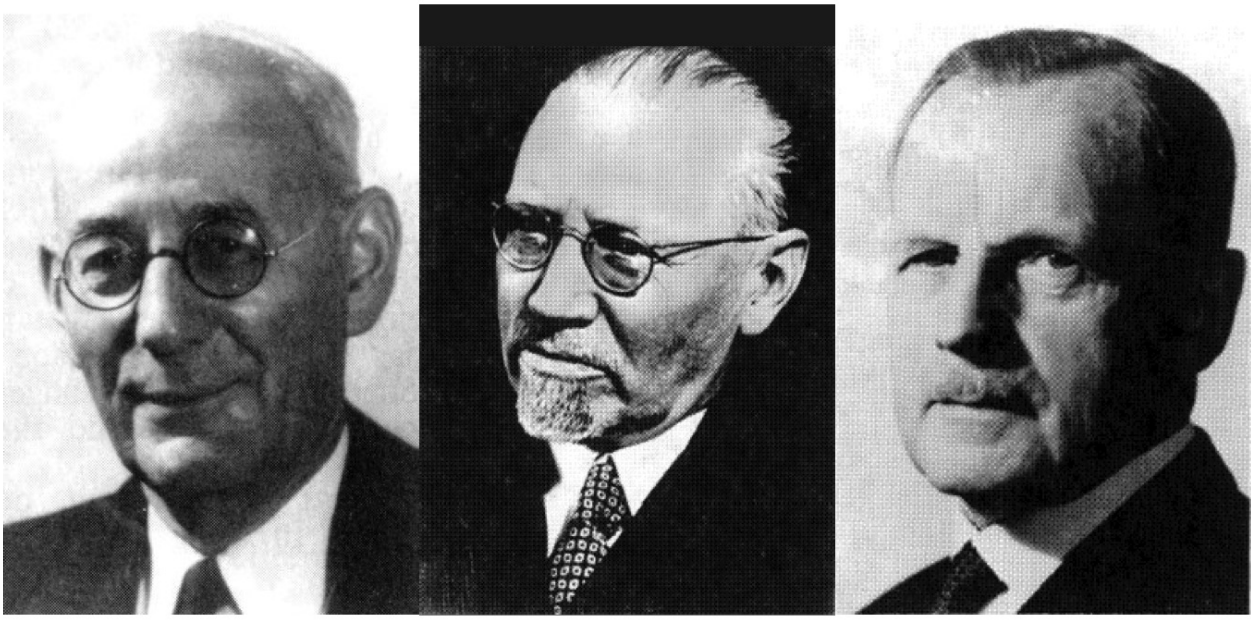
Ernst Eckert (1904–2004)

Leo Graetz (1856–1941)

Franz Grashof (1826–1893)



Max Jakob (1879–1955)

Wilhelm Nusselt (1882–1957)

Ernst Schmidt (1892–1975)

Figure 7.64: Scientists such as Ernst Eckert, Leo Graetz, Franz Grashof, Max Jakob, Wilhelm Nusselt, and Ernst Schmidt carried out measurements and calculations of different modes of heat transfer.

Ernst Eckert (Austrian/German, 1904–2004) studied the fundamental principles of heat transfer and then applied those to jet engines during World War II. After the war, he came to the United States, where he continued his research on heat transfer and its applications. A dimensionless number, the Eckert number, is named in his honor and still widely used in calculating heat transfer dissipation during fluid flow. His obituary provided some details from his life [Jean 2004]:

> Ernst R.G. Eckert's 100th birthday party and symposium will continue as planned in September despite the July 8 death of the internationally renowned aeronautical research scientist and University of Minnesota professor emeritus.
>
> The West St. Paul resident was a specialist in heat transfer—the process in which heat moves from one medium to another—and was recognized for exploring new methods of cooling jet turbines so they wouldn't burn up in space.
>
> Eckert's seven decades of research and more than 550 published scientific papers and books significantly contributed to the development of thermodynamics. He developed the "Eckert Number"—a formula used to calculate high-speed heat transfers.
>
> "One of the things my father was proudest of was that he changed the field of thermodynamics," said Karin Winter, one of Eckert's daughters who was visiting from her home in Amherst, Mass. "My father was extremely modest, and he had a lot of grace, so people loved him. He was always forward-looking and positive."
>
> She recalled that when she was a German literature student at Stanford University, mechanical engineering students would ask her to autograph her father's textbooks. Eckert, a native of Prague, Czechoslovakia, (then part of the Austria-Hungary Dual Monarchy), graduated from the German Institute of Technology in Prague in 1927 and received his doctorate in 1931.
>
> "He used to joke with us kids that he changed citizenship several times without ever leaving home," Winter said.
>
> He was a World War II rocket and jet engine scientist at the Aeronautical Research Institute in Braunschweig, Germany, beginning in 1938 and professor at the German Institute of Technology.
>
> Eckert also held a place in history because he was one of more than 200 German scientists the U.S. government invited here after the war in 1945 under "Operation Paperclip." He joined the staff of Wright-Patterson Air Force Base in Dayton, Ohio, to continue his research on jet propulsion. He became a U.S. citizen in 1950.
>
> He joined the University of Minnesota in 1951 and became one of its first Regents' professors in the late 1960s. Later, Eckert became involved in researching how to turn solar energy into electric power.
>
> "He was an excellent teacher," said University of Minnesota Professor Emeritus Emil Pfender, who worked with Eckert for more than 30 years in the mechanical engineering

> department. “People really enjoyed his lectures because he really could explain things very well.”
>
> Eckert received several honorary doctorate degrees and awards, including the American Society of Mechanical Engineers’ first Max Jakob medal for outstanding engineering in 1961, and a Fulbright Award in 1962.

Leo Graetz (German, 1856–1941) conducted research in heat conduction, thermodynamics, radiation and radiative heat transfer, frictional heating, and many other areas of physics and engineering. His name remains associated with the Graetz number, a dimensionless number that is helpful in calculating heat transfer in heat exchanger pipes. The *Journal of Heat Transfer* described him as one of the pioneers of heat transfer [http://www.seas.ucla.edu/jht/pioneers/pioneers.html]:

> Leo Graetz was a German Physicist born at Breslau, Germany on September 26, 1856. He studied Mathematics and Physics at Breslau, Berlin and Strassburg. In 1881, he became the assistant to A. Kundt at Strassburg and in 1883 he went to the University of München where he became a Professor in 1908 and occupied the Second Chair for Physics parallel to Roentgen. His scientific work was first concerned with the fields of heat conduction, radiation, friction and elasticity. After 1890, his work focused upon problems of electromagnetic waves and cathode rays.

Franz Grashof (German, 1826–1893) made major discoveries across several fields in engineering, including heat transfer, fluid mechanics, the strength of materials, and other topics. He is memorialized with the Grashof number, a dimensionless number that is important in calculations of natural convection. The American Council of Learned Societies listed some of his important contributions [ACLS 2000, p. 369]:

> Studied and taught at the Gewerbe-Institut in Berlin; director of Office of Weights and Measures. Founding member (1856), editor, and long-time director of the Verein Deutscher Ingenieure (VDI). Later taught at the Polytechnikum in Karlsruhe. Authority on mechanical engineering in its broadest sense. Influenced a generation of engineers by bringing mathematical and scientific considerations to the burgeoning problems of the steam-engine age. Was first to present fundamental equations of theory of elasticity, in a text on strength of materials. Name perpetuated in the dimensionless Grashof number of heat transfer in free-convection flow systems for the transition from laminar to turbulent flow, and the Grashof criterion used in kinematics for establishing whether one link of a four-bar chain can rotate completely.

Max Jakob (German, 1879–1955) worked on many mechanisms and applications of heat transfer over his long career. In 1936, he fled Germany for the United States, where he continued his research for many more years. His name is tied to the Jakob number, a dimensionless number that is extremely useful for calculating heat transfer involving condensation or evaporation. The *Journal of Heat Transfer* explained Jakob’s importance for the field of heat transfer [http://www.seas.ucla.edu/jht/pioneers/pioneers.html]:

> Max Jakob was a German Physicist, born July 20, 1879, in Ludwigshafen, Germany. He studied Electrical Engineering at the Technical University of Munchen where he

> graduated in 1902. He was awarded a Diploma Ingenieur in Applied Physics in 1903, and the degree of Doctor Ingenieur in 1904. From 1903 until 1906, he was an assistant to O. Knoblauch at the Laboratory for Technical Physics and later joined the Physikalisch-Technische Reichsanstalt at Berlin-Charlottenburg in 1910, where he started his career in thermodynamics and heat transfer. He conducted a large amount of important work in these fields, covering such areas as steam and air at high pressure, devices for measuring thermal conductivity, the mechanisms of boiling and condensation, flow in pipes and nozzles and much more. During this time, he wrote over 200 technical papers and was a prolific source of critical reviews, articles and discussions. In 1936, he emigrated to the United States, and began a one-year lecture tour sponsored by ASME. He became a research professor at the Illinois Institute of Technology and a Consultant in Heat Transfer Research for the Armour Research Foundation. In 1942, he founded and became the first director of IIT's Heat Transfer Laboratory. His long years of research resulted in significant contributions to the literature of the profession; nearly 500 books, articles, reviews and discussions have been published bearing his name.

Wilhelm Nusselt (German, 1882–1957) made numerous important discoveries in heat transfer, including several different heat transfer mechanisms and applications. He is remembered with the Nusselt number, the ratio of convective vs. conductive heat transfer. The American Council of Learned Societies summarized his contributions [ACLS 2000, p. 654]:

> Studied mechanical engineering at Technischen Hochschulen of Munich and Charlottenburg (Berlin); received doctorate from Munich (1907). Held various teaching and industrial positions until 1925, when he was named to the chair in theoretical mechanics at the Technische Hochschule in Munich (retired 1952). Nusselt was the first significant contributor to the subject of analytical convective heat transfer. In "The Basic Law of Heat Transfer" (1915) he set up the dimensionless functional equations for both natural and forced convection, thus making it possible for experimentalists to generalize limited data; in "The Film Condensation of Steam" (1916) he provided a simple description of the film condensation of any liquid by linearizing the temperature profile and ignoring inertia in the liquid. He later provided an important description of the similarity between heat and mass transfer (1930), and published a book on technical thermodynamics (2 vols.; 1934, 1944).

Ernst Schmidt (German, 1892–1975) worked on conduction, convection, condensation, and radiative heat transfer, discovering important new information on each of those mechanisms. His name remains associated with the Schmidt number, a dimensionless number that makes an analogy between mass transfer and heat transfer. The *Journal of Heat Transfer* lauded his accomplishments [http://www.seas.ucla.edu/jht/pioneers/pioneers.html]:

> Ernst Schmidt was a German scientist and pioneer in the field of Engineering Thermodynamics, especially in Heat and Mass Transfer. He was born on February 11, 1892 at Vogelsen, near Luneburg, Germany. He studied Civil and Electrical Engineering at Dresden and Munchen and joined the Laboratory for Applied Physics at the Technical University, Munchen, in 1919 (which was then under the direction of Oscar Knoblauch). One of his early research efforts there was a careful measurement of the radiation properties of solids, which caused him to propose and develop the use of aluminum foil as

> an effective radiation shield. In 1925, he received a call to come serve as Professor and Director of the Engineering Laboratory at the Technical University in Danzig. Here he published papers on the now well known "Graphical Difference Method for Unsteady Heat Conduction" and on "The Schlieren and Shadow Method" to make thermal boundaries visible and to obtain local heat-transfer coefficients. He was the first to measure the velocity and temperature field in a free convection boundary layer and the large heat-transfer coefficients occurring in droplet condensation. A paper pointing out the analogy between heat and mass transfer caused the dimensionless quantity involved to be called the "Schmidt Number." In 1937, he became the Director of the Institute for Propulsion of the newly founded Aeronautical Research Establishment at Braunschweig and Professor at the University there. In 1952, Schmidt occupied the Chair for Thermodynamics at the Technical University of München which before him had been held by Nusselt. Being strongly involved in the development of the international steam tables, Schmidt continued his scientific activity after his retirement in 1961 and until his death in 1975. In recognition of his work, he received numerous honors and awards, including the Ludwig Prandtl Ring, the Max Jakob Award and the Grashof Commemorative Medal.

In the German-speaking world, there was an enormous amount of overlap between investigations of the fundamental mechanisms of heat transfer and research on many examples and applications of heat transfer, including:

- High-temperature and high-pressure chemistry (Section 3.2)
- Physical chemistry (Section 3.6)
- High-temperature ceramics (p. 667)
- High-temperature metal alloys (p. 689)
- Heat transfer within the Earth, ocean, atmosphere, and extraterrestrial bodies (Chapter 4)
- Thermal physics (Section 5.5)
- Internal combustion engines (Section 7.3)
- Nuclear engineering (Sections 8.7, 8.8, and 8.9)
- Aerodynamics (Section 9.2)
- Jet engines (Section 9.3)
- Rocket engines (Sections 9.6, 9.7, 9.8, 9.9, and 9.10)

7.5 Civil Engineering and Architecture

German-speaking creators made numerous important contributions in the areas of civil engineering and architecture.[5] Only a few illustrative examples are discussed in this section:

7.5.1. Stress, strain, and bridge design

7.5.2. Autobahn high-speed road system

7.5.3. Kitchen design

7.5.4. Other creations in civil engineering and architecture

7.5.1 Stress, Strain, and Bridge Design

Figure 7.65 shows examples of German-speaking scientists who made measurements and developed mathematical formulas for various types of stress and strain in materials:

- August Wöhler (1819–1914) analyzed the bending or deflection of beams under stress, and also produced curves showing the effects of fatigue or repeated stresses in metals.
- Franz Grashof (German, 1826–1893) wrote a textbook on the strength of materials, developed the fundamental equations of elasticity in materials, and also made important discoveries in heat transfer (pp. 1387, 1389).
- Christian Otto Mohr (German, 1835–1918) created the Mohr's circle method that is still used to analyze combinations of stresses.
- Heinrich Müller-Breslau (German, 1851–1925) greatly improved the theory of beams and frames, wrote textbooks on the strength of materials and structural mechanics, and designed airship frames and other structures (p. 1645).
- Wilhelm Flügge (German, 1904–1990) developed the theory of stresses and strains in hollow structures such as fuel tanks and aircraft fuselages.

German-speaking experts also applied their knowledge about stress and strain to design larger and better bridges and other structures:

- Wilhelm August Julius Albert (German states, 1787–1846, Fig. 7.66) studied metal fatigue in 1829. In 1834, he invented wire rope or cable and used it in the first construction projects.
- In 1872, Adolf Bleichert (German, 1845–1901, Fig. 7.66) used wire cable to invent the modern system of cable cars for carrying people and cargo. Bleichert and the company he founded went on to build cable car systems around the world.
- John Roebling (German states, 1806–1869, Fig. 7.67) designed many large-scale projects such as the Brooklyn Bridge (which was completed after his death by his oldest son and daughter-in-law).
- Albert Fink (German, 1827–1897, Fig. 7.68) was famous for developing truss bridges.
- Franz Dischinger (German, 1887–1953, Fig. 7.68) created both cable-stayed bridges and prestressed concrete.

7.5.2 Autobahn High-Speed Road System

Just as the German-speaking world invented internal combustion engines and vehicles to use them, it also created a revolutionary large-scale road system suitable for those vehicles. The German autobahn was designed in the 1920s and built in the 1930s. Figure 7.69 illustrates key aspects of the autobahn's design: one-way multilane roads traveling in each direction, separated by a median, and periodic off- and on-ramps for gas stations and exits. Figure 7.70 also shows examples of early German autobahn bridges, which were necessary both to pass over valleys and rivers and also to divert intersecting roads over or under the autobahn.

The autobahn served as the model for high-speed road networks that were built later in other countries around the world. For example, BIOS 1419, *German Autobahn Bridges* reported an Allied study of the autobahn after World War II:

> The Reichsautobahn is essentially a road system for the use of power driven vehicles at considerable speeds, and in order to achieve this end with safety, complete segregation of the traffic in either direction was adopted, and all road intersections on the same level avoided. Pedestrians, cyclists and horse drawn vehicles were forbidden to use these roads, so that no provision was necessary for footpaths, with a consequent reduction of the overall width required.
>
> On the other hand, complete grade separation at intersections made it necessary to build numerous bridges. [...]
>
> In the main, the construction of the autobahnen and their bridges was carried out during the six years, 1934 to 1939. Prior to this, preparatory work and designs had been prepared, while even after 1939, during the war years, a limited amount of work was done.

[For other examples of postwar Allied studies of the autobahn, see BIOS 575; BIOS 917; BIOS 918; FIAT 518].

Dwight Eisenhower was instrumental in copying the autobahn in the United States. In 1919, Eisenhower participated in a military training convoy across the United States and discovered how poorly suited U.S. roads were for automobiles at that time. During World War II, Eisenhower led U.S. forces into Germany and realized how useful the autobahn was. In the 1950s, Eisenhower became the U.S. president and successfully lobbied for the United States to begin construction of an autobahn-like system of interstate roads. U.S. highway historian Richard Weingroff explained [Weingroff 2003]:

> Although the 1919 convoy shaped Eisenhower's views, his perspective would be supplemented years later by his observations of the German autobahn network of freeways.
>
> Construction of the first segment of the autobahn began in 1929 and was dedicated on August 6, 1932. When Adolf Hitler assumed power as Chancellor of the Third Reich in 1933, he took over the program, claiming it for his own. The 23-kilometer (14-mile) expressway between Frankfurt and Darmstadt, which opened on May 19, 1935, was the

> first section completed under Hitler. By December 1941, when wartime needs brought construction to a halt, Germany had completed 3,864 kilometers (2,400 miles), with another 2,496 kilometers (1,550 miles) under construction.
>
> From the outset of World War II in Europe, the autobahn proved to be a key asset to Germany. The German blitzkrieg ("lightning war"), which involved massive coordinated air and ground attacks to stun opponents, was a key to the German defeat of Poland in 1939 and Belgium, Luxembourg, and the Netherlands in 1940; and the advance to within 480 kilometers (300 miles) of Moscow in 1941. The highway network also enhanced Germany's ability to fight on two fronts—Europe in the west, the Soviet Union in the east. [...]
>
> In the immediate aftermath of the war, Eisenhower was the military head of occupied Germany. Writer Phil Patton pointed out in Open Road that in this capacity, "Eisenhower oversaw the 'debriefing' of the Reich, the creation of a series of reports that include close study of the Autobahns."
>
> Like so many American highway engineers and government officials who had visited Germany during the 1930s, Eisenhower had been impressed by the autobahn. Years later, he would explain that "after seeing the autobahns of modern Germany and knowing the asset those highways were to the Germans, I decided, as President, to put an emphasis on this kind of road building. ... The old [1919] convoy had started me thinking about good, two-lane highways, but Germany had made me see the wisdom of broader ribbons across the land."

Fritz Todt (German, 1891–1942) established the Organisation Todt in 1933 and ran it until his death in a mysterious plane crash in 1942 (likely an assassination by his political rivals or by Allied agents). Organisation Todt designed and built massive government civil engineering projects, somewhat like the U.S. Army Corps of Engineers (Fig. 7.71).

After Fritz Todt's death, formal control of Organisation Todt was granted to Albert Speer. However, direct management of Organisation Todt was carried out by Todt's former deputy, Franz Xaver Dorsch (German, 1899–1986).

Fritz Todt, Franz Xaver Dorsch, and the rest of Organisation Todt built the autobahn in the 1930s. During World War II, they built the heavily fortified Atlantic Wall along the entire western coast of German-controlled territory, as well as the similarly fortified Siegfried Line or Westwall along the entire western border of Germany itself.

After the war, Dorsch continued to work on a wide range of projects in West Germany, and also consulted for the United States.

7.5.3 Kitchen Design

Early kitchens had typically either been dedicated rooms staffed by servants in affluent households, or improvised tools gathered around a heating stove in more common households. Margarete Schütte-Lihotzky (Austrian, 1897–2000, Fig. 7.72) revolutionized the concept of the kitchen by designing a separate, standardized, small room that almost every household could use. By 1926, she created the "Frankfurt Kitchen," which ultimately became the standard kitchen design for apartments and small or medium houses worldwide. (The Frankfurt Kitchen was later adopted and heavily promoted by designers in Sweden, and thus was often incorrectly attributed as the "Swedish Kitchen.") Sarah Archer, an expert on the history of kitchens, described the importance of Schütte-Lihotzky's design [Archer 2019]:

> Margarete Schütte-Lihotzky (1897–2000) was the first Austrian woman ever to qualify as an architect. Following World War I, she was tasked with the design of standard kitchens for a new housing project by city planner and architect Ernst May. The Great War left rubble and a desperate housing shortage in its wake, but it also opened the way for new ideas and new designs. [...]
>
> Schütte-Lihotzky conceived of the Frankfurt Kitchen as a separate room in each apartment, which was a design choice that had previously applied only to the cavernous kitchens that served great houses. [...]
>
> The Frankfurt Kitchen featured an electric stove, a window over the sink, and lots of ingenious built-in storage including custom aluminum bins with a spout at one end. These bins could be used to store rice, sugar, or flour, then pulled out and used to pour the ingredients into a mixing bowl. The kitchen lacked a refrigerator, but in almost every other way, it was thoroughly modern. There was no clunky cast-iron stove, and no mismatched pieces of wooden furniture that had been drafted into kitchen duty. [...]
>
> Margarete Schütte-Lihotzky introduced design ideals that still hold sway over our living spaces. Recognition for her design spread slowly but steadily. [...]
>
> But in 1927, three different versions of the design were shown at a major Frankfurt exhibition. In the '30s, it was written up in the German, English, and French press, and attracted the attention of France's housing minister, who decided he wanted to commission 260,000 units inspired by its design. [...]
>
> While it transformed kitchen design in the 20th century, in certain ways the Frankfurt Kitchen lent more inspiration to new suburban homes than it did to their urban counterparts. This is partly because there was much more new construction in American suburbs following World War II, while large cities tended to be comprised mostly of renters who had to accept their kitchens as they were. The Frankfurt ideals of rational design, optimal work surfaces, color, and smart storage both took shape and grew in size once they took root in suburban ranch homes.

Figure 7.72: Margarete Schütte-Lihotzky created the standard “Frankfurt kitchen” design in 1926.

7.5.4 Other Creations in Civil Engineering and Architecture

Rudolf Virchow (German, 1821–1902, Fig. 2.4), Max Joseph von Pettenkofer (German, 1818–1901), James Hobrecht (German, 1825–1902), and Karl Imhoff (German, 1876–1965) designed sewage collection and treatment systems that revolutionized sanitation and health, and that were ultimately used worldwide. See Fig. 7.73.

Max Giese (German, 1879–1935) and Fritz Hell (German?, 18??–19??) invented the concrete pump in 1927; see Fig. 7.74. Jacob Kweimn (Dutch, 18??–19??) developed an improved concrete pump in 1932. The ability to pump liquid concrete completely transformed modern construction methods.

Philip Deidesheimer (German, 1832–1916) studied at the Freiberg University of Mining and moved to the United States in 1852. He invented (or possibly brought from Germany) the approach known as square-set timbering, which uses a sturdy wooden framework to support large three-dimensional cavities in mining (Fig. 7.75). No later than 1860, Deidesheimer was using square-set timbering in mines in the United States.

In 1887, Ernst Hubbard (Austrian?, 18??–19??) conducted the first experiments trying to develop useful particle board [Hubbard 1887]. In 1932, Max Himmelheber (German, 1904–2000) and Alfred Schmid (German, 1899–1968) perfected and patented particle board and machines to produce it [Sauer 2016]. The production and use of particle board spread throughout the German-speaking world during World War II and was transferred to other countries after the war. See Fig. 7.76.

Walter Gropius (German, 1883–1969) and Ludwig Mies, also known as Ludwig Mies van der Rohe (German, 1886–1969), created Bauhaus architecture and helped to create the International Style of architecture (Fig. 7.77).

Artur Fischer (German, 1919–2016, Fig. 7.77) invented split plastic wall plugs, Fischertechnik construction toys, and the synchronized photo flash.

Karl Fiebinger (Austrian, 1913–2014, Fig. 7.77) developed revolutionary methods that made it possible to create enormous, fully equipped, bomb-proof underground installations; he worked for Germany during World War II and for the United States after the war.

Veröffentlicht am 1. April 1936

Gesuch eingereicht: 11. Juli 1932, 18 Uhr. — Patent eingetragen: 31. Januar 1936.

HAUPTPATENT

Prof. Dr. Alfred SCHMID, Berlin-Dahlem, und
Dipl. Ing. Max HIMMELHEBER, Karlsruhe (Deutschland).

Holzähnliche Masse und Verfahren zu deren Herstellung.

Gegenstand vorliegender Erfindung ist ein holzähnliches Produkt, sowie ein Verfahren zu dessen Herstellung.

Erfindungsgemäße holzähnliche Massen besitzen dem natürlichen Holz gegenüber infolge ungerichteter Lagerung den Vorteil völlig homogener Struktur, sind im übrigen aber in allen Eigenschaften, insbesondere Gewicht, Härte, Bearbeitbarkeit usw. dem Holz weitgehend vergleichbar. Es handelt sich sozusagen um ein homogenisiertes Holz, das alle guten Eigenschaften des Naturholzes aufweist, zum Teil sogar wesentlich verbessert, dabei aber alle jene Nachteile vermeidet, welche die Holzverarbeitung von jeher so schwierig gemacht haben. Das neue Produkt ist dem Naturholz überall dort überlegen, wo dessen gerichtete Faserstruktur zu starken Formänderungen unter atmosphärischen Einflüssen Anlaß gibt, also namentlich im gesamten Anwendungsgebiet des sogenannten Sperrholzes, da Quellung und Schrumpfung, sofern sie überhaupt noch auftreten, was sich nach der speziellen Herstellungsweise richtet, infolge der homogenen Struktur niemals in einer Richtung bevorzugt wirken können. Nicht zuletzt bietet das Verfahren zur Herstellung dieses „Homogenholzes“ den außerordentlichen Vorteil, das Produkt nach Form und Charakter in den denkbar weitesten Grenzen variieren zu können. Man hat es in der Hand, feinfaserige oder grobfaserige, spezifisch leichte oder dichte Stücke von fast beliebigem Härtegrad und in jeder Form herzustellen.

Es ist verschiedentlich versucht worden, aus Faserstoffen, wie Holzschliff, Zellulose, Stroh und Baumwolle usw. holzartige Produkte herzustellen, die als Holzersatz dienen sollen. Neben dem einfachen Zusammenpressen der genannten Substanzen hat man vor allem durch Verfilzung der Faserstoffe dieses Ziel zu erreichen versucht. Dabei sei mit Verfilzung jene eigentümliche Verbindung von Fasern bezeichnet, die dadurch zustande kommt, daß die zunächst in Wasser

Underground installations

Figure 7.77: Walter Gropius and Ludwig Mies (also known as Ludwig Mies van der Rohe) created Bauhaus architecture and helped to create the International Style of architecture. Artur Fischer invented split plastic wall plugs and Fischertechnik construction toys. Karl Fiebinger designed huge, sophisticated underground installations in wartime Germany and the postwar United States.

7.6 Projectile Weapons

German-speaking creators made many important innovations regarding projectile weapons, including[6]:

7.6.1. Guns

7.6.2. Artillery

7.6.3. Shaped-charge anti-tank weapons

7.6.4. Electromagnetic railguns

7.6.5. Flamethrowers

7.6.1 Guns

Gaspard Kollner (Austrian, 14??–15??) and Augustus Kotter (Nuremberg, 14??–15??) are credited with inventing rifled gun barrels around 1498–1520. See Fig. 7.78.

Around 1580–1597, Hans Stopler (Nuremberg, 15??–16??) was the first or one of the first gunsmiths to use a revolving section for multiple bullets, shown in Fig. 7.79.

Johann Nikolaus von Dreyse (Thuringia, 1787–1867) invented the bolt-action rifle in 1824. His Dreyse Zündnadelgewehr bolt-action rifle was mass-produced from 1840 onward (Fig. 7.80).

Building upon von Dreyse's work, the brothers Peter Paul Mauser (German, 1838–1914) and Wilhelm Mauser (German, 1834–1882) created the Gewehr 71 bolt-action rifle in 1871. The Mauser company later developed improved versions, including the Gewehr 98 (1898) and Karabiner 98 kurz (1935), as well as the scaled-up Tankgewehr 18 (1918), which was the first anti-tank rifle. See Fig. 7.81.

As shown in Fig. 7.82, Hugo Borchardt (German, 1844–1924) developed the world's first self-loading, semi-automatic pistol, the Borchardt C93, in 1893. Georg Luger (Austrian, 1849–1923) improved upon that design to create the Luger semi-automatic pistol in 1900.

The German [?] brothers Fidel (18??–19??), Friedrich (18??–19??), and Josef Feederle (18??–19??) developed a different semi-automatic pistol design, the Mauser C96, in 1896; see Fig. 7.83.

---

[6] For coverage of different aspects of this area, see especially: Bishop 2014; Bull 2004; DK 2014; Echle 1979; Engelmann and Scheibert 1974; Gander and Chamberlain 1979; Götz 1990; Hogg 1997, 1999, 2001; Jäger 2001; Klein 1977; Ortner 2007; Romanych and Rupp 2013; Senich 1982, 1987; Taube 1979, 1981; Wictor 2007; Wollert et al. 2008; Zaloga and Dennis 2016.

Based on the earlier Luger design, Fritz Walther (German, 18??–19??) created the more advanced Walther PP in 1929 and Walther P 38 in 1938. See Fig. 7.84. Many modern handguns still use the same designs and features as those guns.

As shown in Fig. 7.85, Theodor Bergmann (German, 1850–1931) and Louis Schmeisser (German, 1848–1917) developed the Maschinengewehr MG 15, an early machine gun, in 1915. Bergmann and one of Louis Schmeisser's sons, Hugo Schmeisser (German, 1884–1953), then developed the Maschinenpistole MP 18, the first practical submachine gun, in 1918. Louis Schmeisser's other son, Hans Schmeisser (German, 18??–19??), also continued to develop and produce various gun designs.

Modern machine gun designs evolved in the German-speaking world:

- Louis Stange (German, 1888–1971, Fig. 7.86) created the Maschinengewehr MG 30 machine gun in 1930.

- Heinrich Vollmer (German, 1885–1961, Fig. 7.87) developed Stange's design into the first general-purpose machine gun, the MG 34, in 1934.

- Based directly on the work of Stange and Vollmer, Werner Gruner (German, 1904–1995, Fig. 7.88) produced a further improved version, the MG 42, in 1942.

These German machine gun designs were widely copied and became the direct ancestors of later machine guns worldwide.

Similarly, modern assault rifles (multipurpose handheld weapons capable of acting as anything from single-shot rifles to fully automatic machine guns) were invented in the German-speaking world. Hugo Schmeisser created the Sturmgewehr StG 44 selective-fire assault rifle in 1944, as shown in Fig. 7.89. Based on Schmeisser's work, Wilhelm Stähle (German, 1901–1974) and Ludwig Vorgrimler (German, 1912–1983) developed an improved version, the Sturmgewehr StG 45, in 1945; see Fig. 7.90. These weapon designs were copied worldwide and gave rise to modern assault rifles such as the AK-47 and M16. In fact, Hugo Schmeisser, Werner Gruner, and other German gun manufacturers were taken to Russia to design guns after the war. Many German gun designers were also interrogated by or went to work for other Allied countries after the war.

As shown in Fig. 7.91, the Krummlauf (curved barrel) modified Sturmgewehr 44, produced in 1944, could shoot around corners. It was equipped with a periscope for seeing around corners as well. Krummlauf rifles were also installed in tank ports to defend the exterior of tanks from close attackers.

In the German-speaking world, innovations in gun design were greatly aided by parallel innovations in optics (see for example Section 6.9) for sighting scopes and by the development of revolutionary infrared imaging or night vision technologies (Section 6.6).

Gaspard Kollner (14??–15??) Augustus Kotter (14??–15??)

Rifled gun barrels (ca. 1498-1520)

corners (1944)
Also equipped with a
periscope for seeing
around corners
(not shown)
Krummlauf with tank port,
designed to defend exterior
of tanks from close attackers

Figure 7.91: The Krummlauf (curved barrel) modified Sturmgewehr 44 could shoot around corners, and was equipped with a periscope for seeing around corners (1944). Krummlauf rifles were also installed in tank ports to defend the exterior of tanks from close attackers.

7.6.2 Artillery

Engineers from the predominantly German-speaking world also made many important innovations in larger-caliber guns or artillery pieces.

In 1674, Menno van Coehoorn (Dutch, 1641–1704, Fig. 7.92) invented the Coehoorn or Coehorn style of mortar, which was widely used until the early twentieth century. He also made other innovations in methods of attacking or defending fortifications. *Encyclopedia Britannica* summarized some of his accomplishments [EB 2010]:

> Dutch soldier and military engineer [...] who made a number of innovations in weaponry and siege-warfare techniques.
>
> The son of an infantry officer, Coehoorn became a captain in 1667 and served in the Dutch War (1672–78) against Louis XIV of France. He attained prominence at the siege of Grave (1674), in which he introduced a highly effective bronze mortar, which subsequently was known as the Coehoorn mortar. His first book on siege techniques appeared in 1682 and was followed by his most important and most widely translated work, *Nieuwe vestingbouw* (1685; “New Fortress Construction”). He perfected a system of fortification suited to level terrain, such as that of the Netherlands, and he advocated a new strategy for citadel defense that involved the active deployment of troops instead of relying only on moats and ramparts.
>
> After greatly assisting in the capture of Bonn (1689) at the outset of the War of the Grand Alliance, Coehoorn fought in the Battle of Fleurus (1690). He improved the fortifications of Namur but lost the city to a French siege in 1692 and did not regain it until 1695. In 1695 he was promoted to master general of the artillery, and in that post he oversaw fortification of several Dutch cities.

In 1880, engineers at Krupp invented the first modern mortars (Mörser), which were rifled breechloaders designed for different calibers of ammunition: 7.5 cm, 15 cm, 21 cm, and other sizes (Fig. 7.93). They could be used either mounted on a wheeled carriage or unmounted on a flat base.

In 1909, engineers at Rheinmetall developed improved trench mortars (Minenwerfer), which were designed for three calibers of ammunition: 7.58 cm (leichte), 17 cm (mittlerer), and 25 cm (schwerer). Like the earlier Krupp mortars, all three sizes were used either mounted on a wheeled carriage or unmounted on a flat base. See Fig. 7.94. The innovative Krupp and Rheinmetall designs prompted other countries to copy and produce similar trench mortars.

Also in 1909, engineers at Skoda demonstrated the 30.5 cm M.11 Mörser siege howitzer, which could fire projectiles with a mass of 384 kg and a caliber of 30.5 cm up to a maximum range of 11.3 km. See Fig. 7.95. M.11 Mörser systems were used by Axis countries in World Wars I and II, and even by some Eastern Bloc countries during the Cold War.

Over the first several decades of the twentieth century, engineers at Krupp developed increasingly sophisticated giant artillery guns, such as:

- The Kurze Marine-Kanone 12 L/16 (also known as Big Bertha or Gamma-Gerät, 1909), which could fire projectiles with masses of 400–1160 kg and a caliber of 42 cm up to a maximum range of 14 km. See Fig. 7.96. Ten of these guns were used in World War I, and one in World War II.

- The Paris Gun (1918, so named because several were used to bombard Paris), which could fire projectiles with a mass of 106 kg and calibers of 22–24 cm up to a maximum range of 130 km. Its projectiles reached altitudes of 42 km, a record that was not broken until flights of the A-4 (V-2) rocket in 1942. See Fig. 7.98. Somewhat improved versions, the 21-cm K 12 (E) railway gun and the 28-cm K 5 (E) railway gun (sometimes called Anzio Annie by the Allies), were produced and used during World War II. (In the 1950s, the United States produced a copy of the 28-cm German gun, officially named the M65 and unofficially called Atomic Annie, since it could fire a specially designed W9 nuclear artillery shell. Was the W9 fission bomb also a copy of a German design?)

- The Schwerer Gustav gun (1941), which could fire projectiles with a mass of 7.1 tons and a caliber of 80 cm up to a maximum range of 47 km. It was the heaviest mobile artillery piece ever built, fired the heaviest artillery shells ever created, and had the largest caliber ever used in combat. See Fig. 7.99. During the war, the Schwerer Gustav gun was used to destroy targets on the Eastern Front, but the gun itself was (mostly) destroyed by Germany at the end of the war to prevent it from being captured intact by Allied troops.

- The Hochdruckpumpe or “V-3” gun (1944), which could fire projectiles with a mass of 140 kg and a caliber of 15 cm up to a maximum range of 165 km [Margry 2001]. See Fig. 7.100. The Hochdruckpumpe was just one of several unrelated projects competing for the title of “V-3,” the next large new weapon system to be publicly announced after the V-2 rocket. (A piloted V-1 cruise missile and multiple large rockets were also called “V-3” at times—see Appendix E.) The Hochdruckpumpe had a clever design in which propellant charges were planted in side chambers at regular intervals along the main barrel, and ignited sequentially as the projectile passed them. One such gun was successfully test fired on the Baltic coast of Pomerania in May 1944, and two guns were used to bombard Luxembourg during the period December 1944–February 1945. The guns were captured and studied by the U.S. Army at the end of the war.

Karl Puff (German, 18??–19??) patented a squeeze bore or tapered bore gun design in 1904. Just as reducing the opening of a garden hose with one’s thumb increases the flow velocity of water, steadily reducing the cross-sectional area of a gun barrel toward the end increases the muzzle velocity of a bullet. Hermann Gerlich (German, 18??–19??) filed more detailed patent applications on squeeze bore designs in 1929 and built such guns; see Fig. 7.101. The German military used squeeze bore guns such as the Pak 41 anti-tank gun (1941).

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed a number of important German innovations for large guns [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, p. 41]:

> Guns ranging from 30 mm to 350 mm calibers were designed to operate without recoil. Certain of these weapons adopted the principle of a "blow-out" disc located at the rear of the powder chamber. This disc was designed to obdurate the powder pressure for a short interval while a given pressure build-up occurs in the chamber, it then releases this pressure to the rear of the weapon. In this manner equal components of momenta are achieved and recoil eliminated.
>
> The advantages of such a development are many. Construction is greatly simplified and elaborate recoil and counter recoil mechanisms are eliminated with savings in weight and material. Thus comparatively large caliber weapons can be adapted for aircraft mounting due to the elimination of recoil and accompanying trunnion stress.
>
> The Germans had made considerable progress with our rigidly mounted tank guns of comparatively large calibers. By the elimination of recoil mechanisms, a considerable saving of space for tank crews was achieved and tank turrets could be fitted with larger guns.
>
> The German design of smooth-bore, high velocity weapons, firing fin-stabilized projectiles was another development worth recording. These weapons resulted in extremely long ranges, excellent accuracy, and lessened gun wear.

7.6.3 Shaped-Charge Anti-Tank Weapons

German-speaking creators also invented shaped-charge anti-tank weapons. See pp. 558–563.

Figure 7.101: Karl Puff patented a squeeze bore or tapered bore gun design for increasing muzzle velocities in 1904. Hermann Gerlich filed more detailed patent applications in 1929 and built such guns. The German military used squeeze bore guns such as the Pak 41 anti-tank gun (1941).

7.6.4 Electromagnetic Railguns

Whereas conventional guns and artillery use the chemical energy of an explosion to propel a projectile and use a barrel to guide the projectile, electromagnetic railguns use the energy of electric and/or magnetic fields to propel a projectile and use rails to guide it. Multiple groups of German-speaking scientists developed and demonstrated electromagnetic railguns during World War II; see Fig. 7.102. The best-documented group was led by Joachim Hänsler (German, 19??–19??), but there were other groups as well.

Hänsler built and demonstrated electromagnetic railguns capable of launching projectiles at velocities up to 1200 meters/second, or over 3.5 times the speed of sound. By 1945, he was continuing to develop larger and faster railguns, planning to reach velocities over 2000 meters/second.[7]

Manfred von Ardenne (German, 1907–1997, p. 1293) led an even larger program to develop and produce electromagnetic railguns. Currently there are only a few known reports in archives that mention his program.[8] These reports demonstrate that during the war, electromagnetic railguns had moved beyond the stage of simple experiments. Very large railguns were being mass-produced in at least 13 factories, and specific launch sites for them were being built and equipped with up to 10 megawatts of dedicated electrical power per railgun.

Even nowadays, electromagnetic railguns are considered to be a high-tech "weapon of the future." The best modern railguns are essentially just larger versions of Joachim Hänsler's and Manfred von Ardenne's 1944–1945 devices, and can now fire projectiles at approximately twice the velocity of Hänsler's wartime railguns. Since Hänsler's (and perhaps von Ardenne's) detailed technical reports and even some of his equipment were brought back to the United States by the Alsos Mission, CIOS, and other teams of investigators in 1945, presumably such modern railguns are directly derived from the wartime German work.

For more information, see Section C.5. Much more archival research should be conducted to elucidate the history of electromagnetic railguns in the German-speaking world, as well as the impact of those innovators and innovations on postwar electromagnetic railguns in other countries.

Joachim Hänsler (19??–19??)

Manfred von Ardenne (1907–1997)

Many other engineers

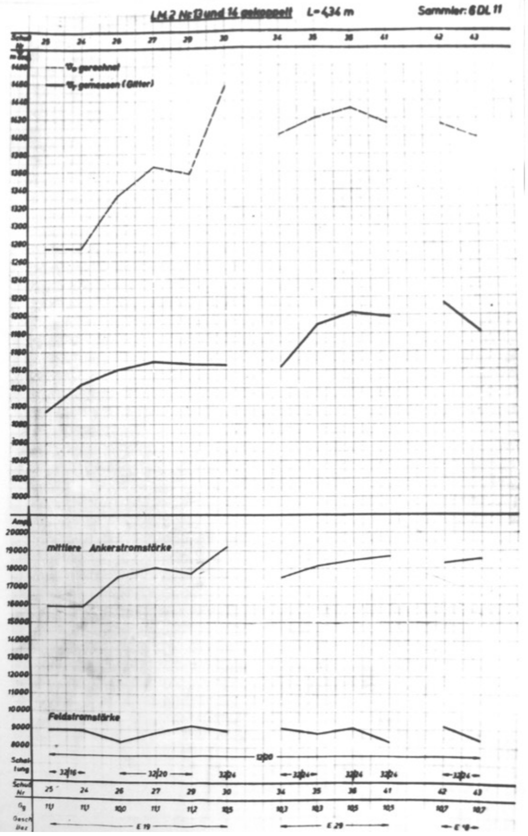

Figure 7.102: During World War II, Joachim Hänsler, Manfred von Ardenne, and other German-speaking scientists developed and demonstrated electromagnetic railguns capable of launching projectiles at velocities of at least 3.6 times the speed of sound. By the end of the war, railguns were being mass-produced for deployment on the battlefield.

7.6.5 Flamethrowers

As shown in Fig. 7.103, Richard Fiedler (German, 18??–19??) invented the modern flamethrower in 1901, and continued to develop improved versions until 1918.

Bernhard Reddemann (German, 1870–1938) and Gábor Szakáts (Austro-Hungarian, 1892–1937) began developing improved flamethrowers in 1904 and 1915, respectively.

Early flamethrowers included:

- The three-person Grossflammenwerfer (Grof, 1912, Fig. 7.103) with a large fuel tank that was not portable.
- The two-person portable Kleinflammenwerfer (Kleif, 1912, Fig. 7.104).
- The one-person portable Wechselapparat (Wex, 1916, Fig. 7.104).

One-person portable flamethrowers were further improved during the Third Reich, resulting in the Flammenwerfer 35 (1935, Fig. 7.105) and the lighter-weight Flammenwerfer 41 (1941, Fig. 7.106).

German-speaking scientists continued to make improvements in flamethrowers throughout World War II, and those improvements were transferred to other countries after the war. For example, BIOS 250, *German Research into Increasing Range and Performance of Flame Throwers*, p. 5, noted several wartime innovations that were identified for transfer to Allied countries in 1945:

> I should like to bring to the attention the following four points arising out of this visit to investigate German flame throwers. The interrogation and search for weapons was guided principally by the endeavor to find out what the Germans were about to develop and what theoretical ideas they had on the projection of fluids, and not so much on existing battle weapons.
>
> 1. B. Smits in Kassel has developed an original idea in the “creep spark plug”, the application of which to the ignition of flame throwers is fool-proof and 100 per cent efficient and was just being applied to their tank flame throwing units.
>
> 2. The Marine Research Station at Kiel (Danisch Nienhof) had developed a dual nozzle flame thrower, which had the advantage of improving the psychological effect of the thickened flame throwing fuel jet besides definitely improving its lethal and anti-personnel efficiency. This overcomes one of the chief criticisms of the thickened fuel flame jet in that in the effort to improve range you lost the anti-morale effect of the old type of flame thrower. The dual combination of Ingolin and heavy density oils is worth noting.
>
> 3. The results of Dr. Buch in Göppingen using the “sago” or dispersed swollen lumps in thickened fuel principle are very interesting in improving the range of the flame thrower into the 200 yards with a 32 mm. nozzle and 40–50 atmospheres pressure.

4. I would recommend the removal of Commander Jentsch and Dr. Eckhardt from the Marine Research Station at Danisch Nienhof to Langhurst or elsewhere in England, on the grounds that they are exceptional practical scientists, who could give us great assistance in the development of oil technology in this country.

I think if handled correctly they would be very willing and successful collaborators in technical developments much required here. Anyhow their stay in Danisch Nienhof is a complete waste of good human material.

Owing to the time factor, the visit could not be completed and the flame throwing research units in Munich and Vienna and an investigation of the Mauser works at Oberndorf should be undertaken. In particular, the Research Laboratory of Professor Ostwald in Munich was the first establishment (1926) to investigate the increase of viscosity of hydrocarbons by the dispersion of soaps in the oils.

7.7 Ocean Engineering

Creators from the predominantly German-speaking scientific world masterminded the development of submarines and related technologies, producing not only undersea- or U-boats that revolutionized warfare during World Wars I and II, but also submarine technologies that were the foundation of postwar submarine designs by the United States, Soviet Union, and other countries.[9]

This section covers the contributions of German-speaking scientists and engineers to:

7.7.1. Early experimental submarines

7.7.2. Military submarines

7.7.3. Bathyscaphes

7.7.4. Rotor ships

7.7.1 Early Experimental Submarines

As shown in Fig. 7.107, Cornelius Drebbel (Dutch, 1572–1633) built a series of oar-propelled wooden submarines in the 1620s, culminating in a demonstration of the largest one in 1624 in the Thames for the British royal court. *Encyclopedia Britannica* explained [EB 2010]:

> Dutch inventor who built the first navigable submarine.
>
> An engraver and glassworker in Holland, Drebbel turned to applied science and in 1604 went to England, where King James I became his patron. He devised an ingenious "perpetual motion clock," actuated by changes in atmospheric pressure and temperature, which greatly enhanced his reputation. In 1620 he completed his "diving boat." Propelled by oars and sealed against the water by a covering of greased leather, the wooden vessel travelled the River Thames at a depth of 12 to 15 feet (about 4 metres) from Westminster to Greenwich. Air was supplied by two tubes with floats to maintain one end above water.
>
> Drebbel also discovered the use of tin compounds as mordants for cochineal, a scarlet dye, and suggested a method of making sulfuric acid by the oxidation of sulfur. Among many other inventions attributed to him are the compound microscope, an improved thermometer, and self-regulating ovens.

Wilhelm Bauer (Bavarian, 1822–1875) built and demonstrated the *Brandtaucher* prototype submarine in 1850, and the larger *Seeteufel* in 1855. He also raised a sunken ship using balloons. See Fig. 7.108. *Jane's Submarines* described his history of submarine development [Hutchinson 2001, pp. 10-11]:

> In 1850, the former artillery non-commissioned officer, Wilhelm Bauer (1822–1975) built the *Brandtaucher* ('Fire Diver') in Kiel, Germany: an unattractive 27-feet long craft with a short, stubby steel hull, a low conning tower right forward at the bows with two bulls-eye portholes, and a displacement of nearly 39 tons. It accommodated three men. Again, it relied on muscle power to drive the screws, via a large treadmill mounted amidships—after earlier tests with clockwork again failed to supply enough power. The aim was to develop a weapon that would disrupt a Danish naval blockade of northern German ports. It was tested to depths of just over 50 feet but was never deployed operationally after the first test, on February 1 1851, nearly became a disaster.
>
> The boat plunged to the sea bottom, 54 feet below the surface and after more than five terrifying hours, Bauer opened the flood valves to equalise the pressure within the hull to allow escape. When the seawater reached the chins of Bauer and his two fellow crewmen, a bubble of air blew the hatch open and all three shot to the surface—to survive. It was the first successful submarine escape.
>
> *Brandtaucher* was later raised from the bottom of Kiel Harbour in 1887 and renovated. This remains the oldest preserved submarine in the world and can be seen today in the Deutsches Armeemuseum, Neuer Garten, Potsdam, Germany.
>
> Four years later, Bauer built the *Seeteufel* ('Sea Devil') for the Russian Navy, a much larger and more ambitious design, with a steel hull, a 13 man crew, and a small engine for use on the surface. The flat, sausage-shaped hull, launched from the Leuchtemburg yard in St Petersburg, on November 2 1855, was 52-feet long and 12-feet wide. The problem of sub-surface propulsion remained intractable with the *Seeteufel* relying on his earlier, cumbersome system of a treadmill-cranked screw. Water ballast was controlled by a system of hand-pumps. The boat made 133 successful dives[...]

Julius Kröhl (Prussian, 1820–1867), shown in Fig. 7.108, built the Sub Marine Explorer prototype submarine during the period 1863–1867. Naval historian Jobst Broelmann provided some insight into Kröhl's otherwise rather mysterious submarine development program [Broelmann 2012, pp. 62–63]:

> Dies Argument soll den deutschen Ingenieur Julius H. Kröhl bewogen haben, ein Unterwasserförderschiff zu bauen, das die Prinzipien von Payerne aufgriff. Ein Angebot von William Henry Tiffany, dem Bruder des Gründers der Firma Tiffany, ermöglichte Kröhl den Bau. Tiffany war Hauptgesellschafter der Pacific Pearl Company, die Perlen im Pazifik ernten wollte und dazu einen geeigneten Tauchapparat brauchte. Das Boot wurde in einem Dock in Brooklyn gebaut und 1866 vorgestellt.
>
> Die längliche Form des Bootes entstand aus einer Reihe hintereinander angeordneter Räume, die wie Taucherglocken unten zu öffnen waren. Am Heck war ein manueller Propellerantrieb vorgesehen. Da bei diesen Apparaten Taucher das Boot durch Luken verlassen sollten, musste ihr Innendruck der Wassertiefe entsprechen oder eine Druckschleuse eingebaut sein. Im ersten Falle glichen sie also einer frei beweglichen Taucherglocke, die ohne Verbindung zur Oberfläche agieren konnte. Getaucht wurde durch einströmendes Wasser, aufgetaucht durch Einblasen von Druckluft.
>
> Das Explorationsschiff Kröhls wurde 1867 für kurze Zeit in Panama eingesetzt. Es wird vermutet, dass die Betreiber der Taucherkrankheit erlagen. Erst 2002 konnte ein Wrack in dieser Region als die ehemalige Konstruktion Kröhls identifiziert werden.

> This argument is said to have persuaded the German engineer Julius H. Kröhl to build an underwater production ship that took up Payerne's principles. An offer from William Henry Tiffany, the brother of the founder of the Tiffany company, enabled Kröhl to build it. Tiffany was the main shareholder of the Pacific Pearl Company, which wanted to harvest pearls in the Pacific and needed a suitable diving apparatus to do so. The boat was built in a dock in Brooklyn and presented in 1866.
>
> The elongated shape of the boat was created from a row of rooms arranged one behind the other, which opened like diving bells at the bottom. A manual propeller drive was provided at the stern. Since divers were supposed to leave the boat through hatches, their internal pressure had to correspond to the water depth or a pressure lock had to be installed. In the first case they resembled a freely movable diving bell, which could operate without connection to the surface. Diving was done by inflowing water, surfaced by blowing in compressed air.
>
> The exploration ship Kröhl's was used in Panama for a short time in 1867. It is assumed that the operators succumbed to the diving sickness. Only in 2002 a wreck in this region could be identified as the former construction of Kröhl.

7.7.2 Military Submarines

Despite the early innovations by Cornelius Drebbel, Wilhelm Bauer, and Julius Kröhl, work on submarine prototypes shifted to France in the late nineteenth century, perhaps due to the fictional inspiration provided by Jules Verne's *Twenty Thousand Leagues Under the Sea* (1870). By the early twentieth century, though, German submarine designers had taken the lead, and continued to lead through World War II.

As illustrated in Fig. 7.109, some key submarine designers included:

- Christoph Aschmoneit (German, 1901–1984): World War II submarines
- Gustav Berling (German, 1869–1943): World War I submarines
- Fritz Bröking (German, 1877–1961): Type VII and Type XXI submarine propulsion
- Ulrich Gabler (German, 1913–1994): Type XXII, XVII A, and XXVI submarines
- Friedrich Schürer (German, 1881–1948): Type VII and Type XXI submarine propulsion
- Hellmuth Walter (German, 1900–1980): air-independent submarine propulsion; V 80 teardrop shape

Figure 7.110 presents plans for the Type UB III U-boat (built 1915–1918), as well as a photo of a Type UB III, the UB-86, shown abandoned and grounded after World War I.

Similarly, Fig. 7.111 shows plans for the Type VII U-boat (built 1935–1945) and a photo of a Type VII, the U-995, now on display at the Laboe Naval Museum. One can see that the Type VII was essentially an updated version of the older Type UB III design.

Figure 7.112 presents plans for the much more advanced Type XXI U-boat (built 1943–1945) and shows three Type XXI U-boats at the German naval base at Bergen, Norway. Figures 7.113–7.118 are photographs of a Type XXI, the U-2540 "Wilhelm Bauer," now on display at the German Maritime Museum in Bremerhaven. The Type XXI submarine design was so advanced for its time that the Allies considered it an extremely serious threat, even very late in the war. For example, the 12 January 1945 Top Secret Cable OUT 1005 from Office of Strategic Services Magruder to Bern Switzerland [NARA RG 226, Entry UD-90, Box 7, Folder BERN—IN OUT 1944–1945] stated:

> German program for new type submarines is perhaps most menacing aspect of German war capabilities due to exceptional defensive characteristics of new submersibles. At present only effective defense is to interfere with their production. I refer to types Roman number 21 and 23. Former of 1600 tons and latter of 200 tons plus. The 21 is particularly dangerous. Both are prefabricated in various places and shipped in parts to launching ports. Productive capacity and assembly speed high.
>
> Please give priority to information permitting air attack on places of manufacture of prefabricated hulls and routes to assembly ports. Also much desired is place of manufacture of new and highly efficient types of Diesel engines and batteries.

Of the 123 Type XXI U-boats in service during the war, 23 were destroyed by Allied attacks and 88 were scuttled by Germany at the end of the war. After the war, the remaining 12 operational Type XXI submarines were divided among the U.S., U.K., France, and Soviet Union and studied very closely (Fig. 7.119) [Breyer 1999, p. 38; Wetzel 1999; NYT 1945-11-22 p. 16a, 1947-02-12 p. 10]. As just one example, on 12 February 1947, the *New York Times* reported:

> The House Armed Services Committee gave unanimous approval today to construction of two new experimental submarines embracing ideas gained from Allied war experiences and seized German U-boats. It approved, subject to House action next week, the Navy's request for authority to spend up to $30,000,000 in already appropriated funds to build the new vessels. The estimated cost of each submarine is from $11,000,000 to $15,000,000.

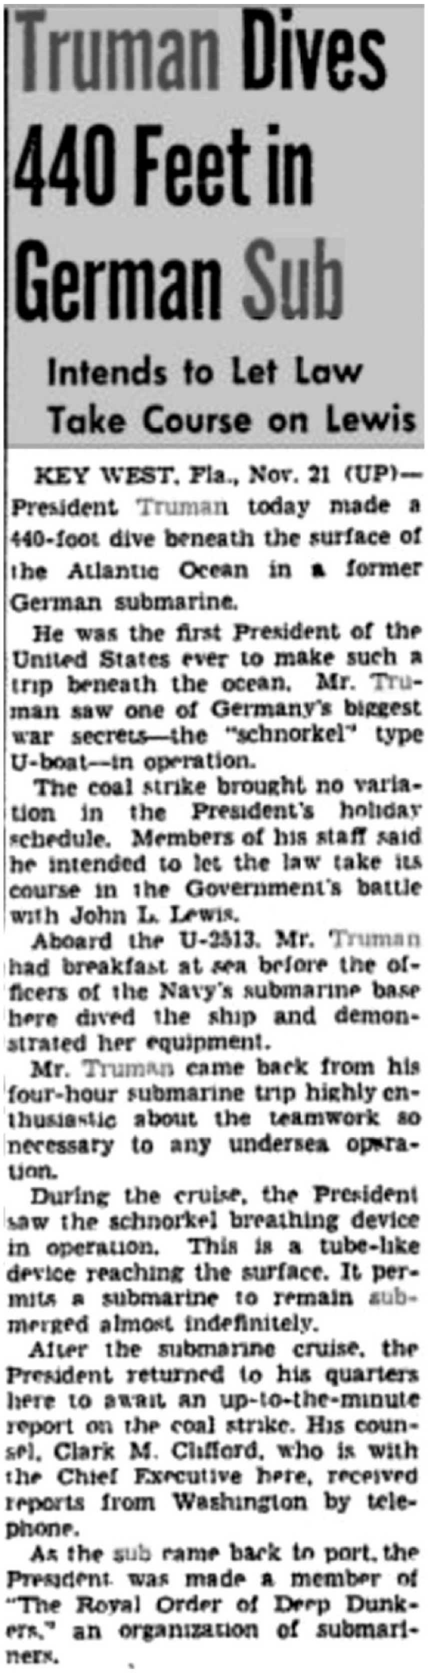
U.S. submarine experts Norman Polmar and Kenneth Moore confirmed that postwar submarines in the United States, Soviet Union, and other countries were based directly on the captured German submarine technology [Polmar and Moore 2004, p. xi]:

> Soviet and U.S. submarines of the Cold War era had the same origins: Their antecedents were German U-boat developments of 1943–1945, especially the Type XXI, the most advanced submarine to go to sea during World War II. The U.S. version of the Type XXI was the *Tang* (SS 563) class, with similar features being incorporated in the *K1*-class "killer" submarines and 52 conversions of war-built submarines in the so-called GUPPY program. The Soviets adopted Type XXI features in the Whiskey and Zulu designs and their successors. The U.S. and Soviet (as well as British) submarine communities also had major interest in German closed-cycle, or "single-drive," submarine propulsion systems, with these submarines being evaluated in the postwar period by Britain and the Soviet Union.

Wartime prototype submarines that utilized a teardrop hull design for high speeds included the V-80 (first demonstrated in 1940) and the *Delphin* (*Dolphin*, first demonstrated in 1944); see Fig. 7.120. Of course, the teardrop design was known much earlier from German airship designs (see Section 9.1). The teardrop hull is sometimes called the *Albacore* hull after the first U.S. submarine to use that shape, the USS *Albacore*, which was designed using captured German submarine designs and launched in 1953.

As illustrated in Fig. 7.121, the United States needed German machines (such as the Trebel balancing machine shown in the photo) in order to make propellers for its postwar submarines such as *Nautilus*, the first U.S. nuclear submarine [NYT 1958-10-09 p. 73].

As shown in Fig. 7.122, a recently declassified CIA report from 1950 (summarizing Soviet work from 1943 to 1948) reveals how dependent postwar Soviet submarines were on captured German-speaking scientists and submarines, torpedoes, missiles, and other technologies from wartime German programs [https://www.cia.gov/readingroom/document/cia-rdp80-00809a000600360061-4.].



Truman Dives 440 Feet in German Sub

Intends to Let Law Take Course on Lewis

KEY WEST, Fla., Nov. 21 (UP)—President Truman today made a 440-foot dive beneath the surface of the Atlantic Ocean in a former German submarine.

He was the first President of the United States ever to make such a trip beneath the ocean. Mr. Truman saw one of Germany's biggest war secrets—the "schnorkel" type U-boat—in operation.

The coal strike brought no variation in the President's holiday schedule. Members of his staff said he intended to let the law take its course in the Government's battle with John L. Lewis.

Aboard the U-2513, Mr. Truman had breakfast at sea before the officers of the Navy's submarine base here dived the ship and demonstrated her equipment.

Mr. Truman came back from his four-hour submarine trip highly enthusiastic about the teamwork so necessary to any undersea operation.

During the cruise, the President saw the schnorkel breathing device in operation. This is a tube-like device reaching the surface. It permits a submarine to remain submerged almost indefinitely.

After the submarine cruise, the President returned to his quarters here to await an up-to-the-minute report on the coal strike. His counsel, Clark M. Clifford, who is with the Chief Executive here, received reports from Washington by telephone.

As the sub came back to port, the President was made a member of "The Royal Order of Deep Dunkers," an organization of submariners.

SECRET

50X1-HUM

In the USSR, submarine construction, together with aircraft construction further development of the V-2 rocket, and the development of a practicable atomic bomb, is a priority project of the armament industry. Prior to the war, the Russian built, at Leningrad, only the standard type submarine of 900 tons displacement, not counting a few experimental types. Only after the war, when the Russians had occupied Berlin and the German Baltic ports and had obtained the German design data and ships, did they take up submarine construction intensively. In 1946, the Russians succeeded in getting a number of the members of the staff of the Glueckauf Engineering Office at Blankenburg in the Harz Mountains -- during the war the central designing office for German submarines -- to return there by offering them high salaries. The construction of the German Type 26 submarine, the so-called Walther submarine, was then resumed. Some of the Blankenburg staff later went to Koenigsberg and to Leningrad, others returned to the Western zone.

The captured U-boats were concentrated at Leningrad and at Kronshtadt. The Russians are working on further development of the German Type 21 submarine. In the summer of 1948, about 15 submarines of this type were under construction at the Leningrad Navy Yard. An interesting improvement instituted by the Russians is the quick-loading mechanism of the bow torpedo tubes. The German quick-loading mechanism did not function properly, but the Russians have improved it to such an extent that all six tubes in the box can now fire three times within 3 minutes.

The Russians are also experimenting with the installing of rocket launchers on Type 21 submarines. The launcher resembles a torpedo tube. It is set up in front of the conning tower, and operated from inside the ship. It will still function when the ship is submerged to half the height of the conning tower. The rockets are powered by liquid fuel, consisting of a hydrocarbon -- nitric acid mixture with automatic ignition. Fuel feed is by compressed air. The rockets have a range of about 7 kilometers, and their accuracy is adequate.

At Odessa, the Russians are building two-man submarines developed from the German design. They are powered by a high-rpm diesel engine. The captain of the submarine can stand up on his seat when the ship is surfaced, and the upper part of his body protrudes from the conning tower. The engineer sits in front of the engine, and can start the engine with a hand crank, in case the battery is run down and no longer has enough power to operate the self-starter. The tower is equipped with a short periscope which is retractable. The submarine carries two torpedoes underneath the hull. This type of submarine is manned only by volunteers. It is capable of a speed of about 12 nautical miles.

The Russians are testing three new types of torpedoes. The first is the well-known acoustic torpedo, which is automatically attracted to the target by the noise of the target's propellers. This version has been developed to a high degree of perfection, and possesses high accuracy. Of course, it still suffers from the disadvantage that the target can tow noise-producing dummies which will deflect the torpedo, provided they operate in the proper frequency range.

The second version used ultrasonic guide beams. The frequency is in the range of 800 kc. The results obtained with this torpedo were very satisfactory up to a distance of 3 nautical miles. The torpedo is not very susceptible to jamming, unless the jamming is tuned exactly to the guide-beam frequency. At large distances, the guidance becomes less reliable, because it is difficult to produce ultrasonic waves at that frequency with a sufficiently large range.

The third version employs infrared radiation for automatic steering, and uses the principle of radar. This design was first developed by the Germans toward the end of the war and then perfected by the German engineers for the Russians. The torpedo is very accurate, even at long ranges, provided the infrared ray generator functions properly. Since this is not always the case, 35 percent of the torpedoes misfire.

SECRET

SECRET

Figure 7.122: A recently declassified CIA report reveals how dependent postwar Soviet submarine technologies were on German-speaking innovators and innovations. New Soviet Weapons. 10 November 1950 [based on intelligence from 1943–1948]. https://www.cia.gov/readingroom/document/cia-rdp80-00809a000600360061-4.

The key features of modern naval mines and torpedoes were developed by creators from the German-speaking world.[10]

While the concept of naval mines had been around for centuries, the chief difficulty was making the mines detonate automatically and reliably, without direct human control or timers. That problem was solved by German inventors in the nineteenth century, as shown in Fig. 7.123. The first practical contact-activated naval mines were created by Moritz von Jacobi (German, 1801–1874) in 1853. His mines used electromechanical contact switches, and they were successfully employed during the Crimean War.

In 1868, Albert Hertz (German, 18??–19??) invented improved mines that used electrochemical contact switches, or "Hertz horns." Inside each metal horn was a fragile glass reservoir of liquid electrolyte; if the horn was bumped, the liquid electrolyte was released into the previously empty space between two electrodes, making a functional electrical battery that detonated the mine. That was a very simple and elegant solution that allowed a deployed naval mine to remain viable for many years. Even in the twenty-first century, many naval mines still use this method.

Self-propelled explosive torpedoes were developed in the 1850s–1860s by a currently unknown Austrian marine artillery officer, Giovanni Luppis von Rammer (Austro-Hungarian/Croatian, 1813–1875), Robert Whitehead (English but worked in Austria, 1823–1905), and Annibale Plöch (Austrian, 1826 or 1836–1906?). See Fig. 7.124. Using their designs, the world's first torpedo factory opened in 1872 in Fiume, Austro-Hungary (now Rijeka, Croatia; Fig. 7.125).

Nikola Tesla (Serbo-Croatian, educated in Austria, 1856–1943) made a revolutionary early advance when he patented and demonstrated a radio-controlled boat or torpedo in 1898 (p. 1207). Building on that invention, Siemens engineers developed the Fernlenkboot remote-controlled explosive motorboat/torpedo in 1911 (Fig. 7.126). Fernlenkboot models came in both radio-controlled and wire-guided versions, carried 700 kg of explosives, could travel up to 56 km/hour, had a range of up to 20 km, and were successfully employed during World War I.

German-speaking creators made numerous other improvements to torpedoes before, during, and after World War I. By World War II, German innovations in torpedo design included improved energy sources such as batteries (in G7e torpedoes) and concentrated hydrogen peroxide (H_2O_2, called Ingolene). Other innovations included improved guidance systems such as preprogrammed pattern running systems (Fat I/II and Lut I/II) and acoustic homing systems (Falke and Zaunkönig). Those innovations in torpedo design were adopted by other countries after the war.[11] See Fig. 7.127.

Schwanzstück (mit Tiefen- und Seitenruder und 2 gegenläufigen Propellern)
Maschinenkammer (mit 4-Zylinder Brotherhood Maschine)

Figure 7.127: Some German innovations in torpedo design included improved energy sources such as batteries (in G7e torpedoes) and concentrated hydrogen peroxide (H_2O_2, called Ingolene). Other innovations included improved guidance systems such as preprogrammed pattern running systems (Fat I/II and Lut I/II) and acoustic homing systems (Falke and Zaunkönig).

German submarine bunkers were also quite sophisticated. For example, as shown in Fig. 7.128, the U-boat bunker Bruno in Bergen, Norway could hold and service up to nine submarines at a time, with six meters of overhead concrete reinforcement to protect them from Allied aerial bombing.

The Goliath low-frequency radio transmitter (Kalbe/Calbe an der Milde) could communicate with submerged submarines around the world. The transmitter was essentially a spiderweb of antennas that stretched 1600 m wide and 200 m high. Once it became operational in 1943, it radiated one million Watts of electromagnetic power [Bauer 1997; Klawitter 1998; AFHRA B1975, frames 1325–1495; https://www.kalbe-milde.de/gol.php]. See pp. 1476–1478. After the war, the Goliath transmitter was extensively studied by western Allied countries and completely removed by and reconstructed in the Soviet Union, inspiring postwar low-frequency radio transmitters for submarine communications in many countries. For example, the U.S. Navy's similar Clam Lake facility in Wisconsin became operational in 1985 (Fig. 7.132).

An especially mysterious and historically important topic is how far wartime Germany may have gotten in developing nuclear power for submarine propulsion, and how much that work influenced and aided postwar work on nuclear submarine propulsion in the United States and other countries. It seems very likely that there was such a wartime program, since Germany was very interested both in developing fission reactors (Appendix D) and also in improving the performance of its submarines (which were limited by needing air to power their diesel engines, except for short periods of fully submerged operation using batteries). Unfortunately there is very little available documentation at present. One intriguing comment long after the war came from Werner Grothmann, who had been Heinrich Himmler's chief adjutant [Krotzky 2002, p. 34; see pp. 3396–3397 regarding this source]:

> Deshalb kann ich auch nichts dazu sagen, was im einzelnen auf Bornholm war, außer daß auch die Kriegsmarine dort etwas machte. Vielleicht mit der Reichspost zusammen. An den Vorüberlegungen zum Atommotor für unsere U boote werden sie dort nicht gearbeitet haben, das lief ja in Berlin bei Rhein und der hatte sich dazu Physiker ausgeliehen, die auch mal beim Heereswaffenamt unter Vertrag standen, aber jedenfalls nicht bei der Reichspost.

> That is why I cannot say anything in detail about what was on Bornholm, except that the German Navy did something there as well. Maybe together with the Reichspost. They would not have worked there on the preliminary considerations for the atomic engine for our submarines; that ran in Berlin with [Admiral Wilhelm] Rhein and he had borrowed physicists, who were also under contract with the Army Ordnance Office, but in any case not with the Reichspost.

Admiral Wilhelm Rhein headed the Navy Weapons Office (Marinewaffenamt, MWA) in Berlin. He assembled a team of scientists (including Otto Haxel, Pascual Jordan, Helmut Hasse, Fritz Houtermans, and others) that worked on applications of nuclear technology for the German navy. Because so few documents from those programs survive (or have been declassified if they do survive), it is currently unclear just how far those programs progressed by the end of the war.

Nonetheless, it is quite intriguing that the zirconium (and possibly other materials, information, and/or expertise) for the first postwar U.S. nuclear submarine was left over from a mysterious wartime German program. See p. 4146–4147 for more information.

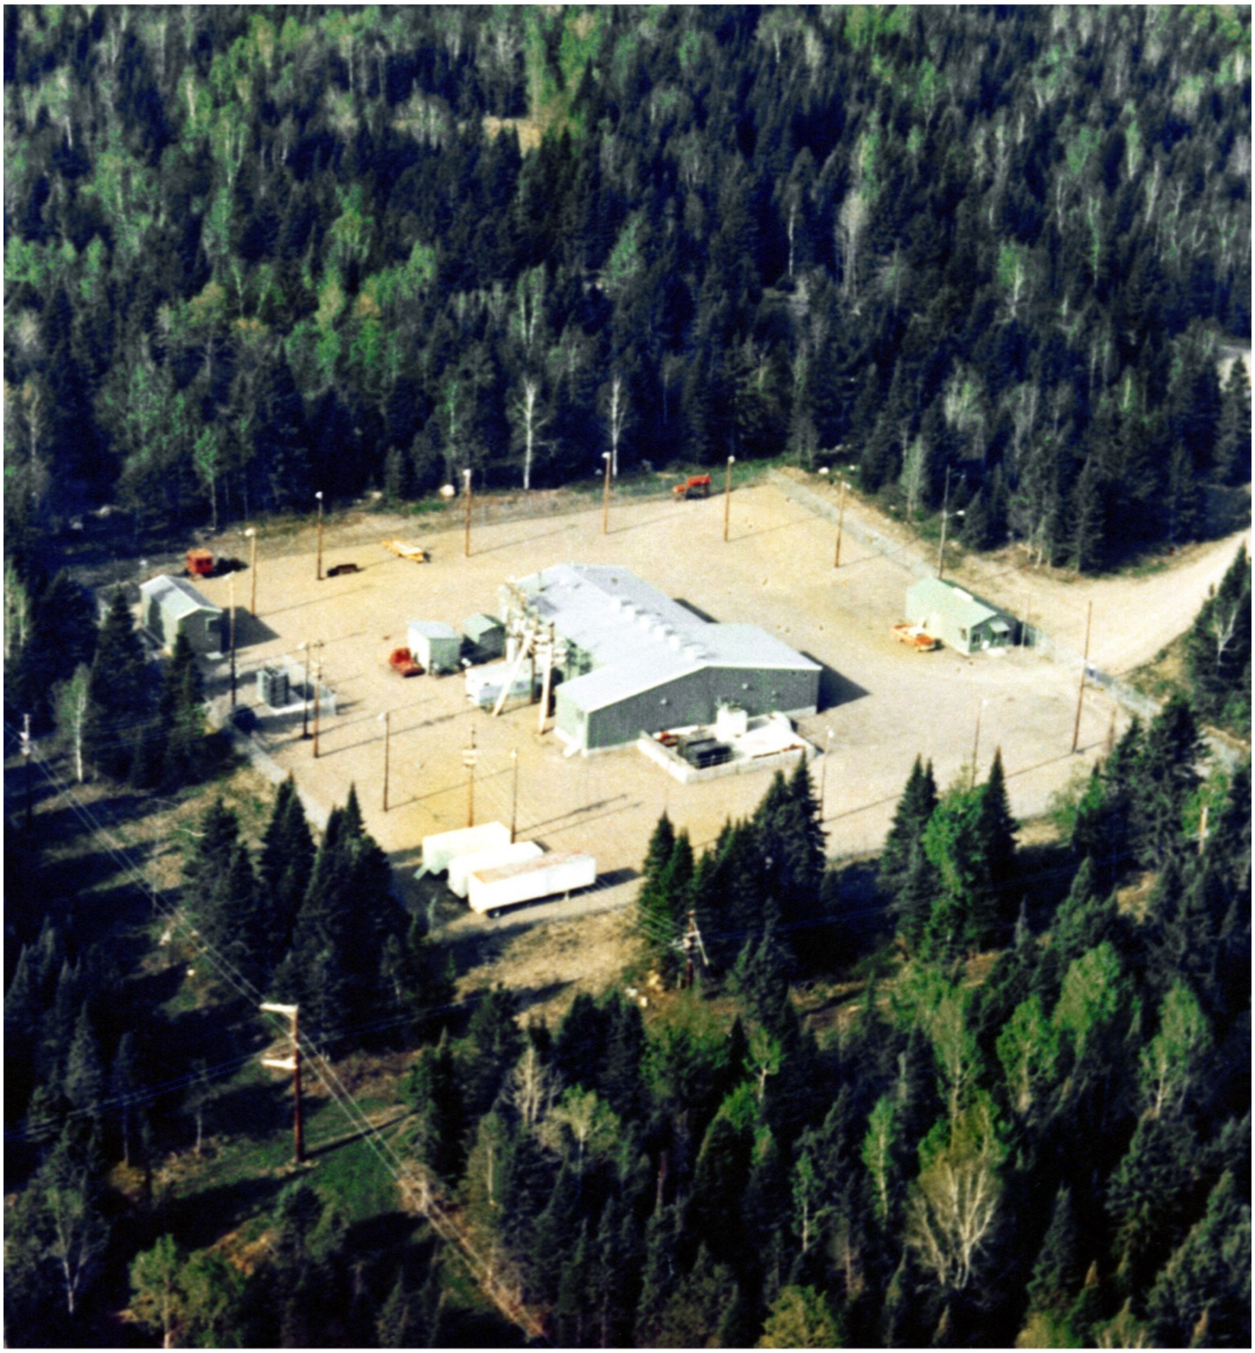
Figure 7.131: The Goliath low-frequency radio transmitter (Kalbe/Calbe an der Milde) could communicate with submerged submarines around the world. It was 1600 m wide and 200 m high, radiated one million Watts of electromagnetic power, and became operational in 1943.



U.S. low-frequency radio transmitter to communicate with submarines (U.S. Navy's Clam Lake facility, Wisconsin, operational in 1985)

Figure 7.132: Inspired by the wartime German Goliath transmitter, other countries later built similar massive low-frequency radio transmitters to communicate with submerged submarines around the world. For example, the U.S. Navy's Clam Lake facility in Wisconsin became operational in 1985. The Soviet Union used the Goliath transmitter itself, disassembled and reassembled by German experts in the Soviet Union.

At the very least, it is clear that wartime Germany adapted gas turbine engines for use in submarines, and that those engines and methods were found and utilized by other countries after the war. For example, BIOS 98, *Report on German Development of Gas Turbines for Armoured Fighting Vehicles*, p. 78, stated:

> Notes on the Interrogation of Dipl. Ing. Heinrich Holzapfel [...]
>
> At Messrs. Bruckner-Kanis he was engaged on the development of turbines operating on the hydrogen peroxide cycle, developed by the Walther Company of Hamburg. In addition he was responsible for the development of gas turbines for torpedo boats.

For another example, see FIAT 291, *Gas Turbine Project for a Schnell Boat Developed by Blohm & Voss, Hamburg.*

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed a number of important German innovations in ocean engineering that were transferred to Allied countries after the war [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 70–71]:

> The Germans had developed submarines which were capable of underwater operation for sustained periods. It was discovered that one German submarine had operated for 40 days without surfacing. This was possible because of the “Schnorkel” which permitted the charging of batteries and the operation of engines while submerged. The “Schnorkel” is a tube-like device extending to the surface while the submarine hull is under water, thereby permitting air intake and exhaust discharge.
>
> Much research had been devoted to closed cycle engines. These engines were intended to supplant the conventional type of Diesel, and permit underwater operation without any air intake. The Germans employed extremely high concentrations of H_2O_2, liquid oxygen, and hydrazine-hydrate as fuels. Investigation revealed that high underwater speeds were achieved by use of these fuels in conjunction with new hull designs. U-boats actually constructed obtained submerged speeds in excess of 24 knots. Submarines fully equipped could sustain a 25 knot speed for 6 hours with an underwater operating radius of 150 miles.
>
> Intensive investigation was conducted regarding German torpedo developments. Torpedoes powered by liquid oxygen [sic: hydrogen peroxide] of 80 to 85% concentration, (Ingoline), were in large scale production. Torpedoes using this type of propulsion were capable of speeds in excess of 45 knots. It was discovered that the Germans had devised a method of employing salt water in torpedo propulsion motors, which obviated the necessity of providing fresh water tanks within the torpedo. The space and weight saving achieved enabled them to construct torpedoes capable of long ranges. Certain of these torpedoes had a range of 21,000 yards at 45 knots.
>
> American and British naval experts have conducted detailed investigations of new German torpedo pistols.
>
> The Germans were found to have used ultra-high boiler pressures and temperatures to attain maximum speed for surface ships, with a minimum of ship’s space devoted to power plants. [...]

Great quantities of highly classified German naval documents were obtained by US and British naval investigators. These documents included the following:

1. General specifications for the construction of ships for the German Navy; other specifications for machinery, and armament installations.

2. Complete plans for the Type 21 and Type 23 submarines and midget U-boats.

3. Plans and specifications for the latest type E-boats with the following characteristics:

   20 cylinder diesels, three 2500 HP motors capable of 42 knots speed, 35 meters long, 5.2 meters beam.

4. Detailed specifications for hull and machinery of the 10,000 ton Deutschland, the 6,000 ton Karlsruhe and Nuremberg, the 26,000 ton battleships Gneisenau and Scharnhorst, projected light cruisers “M” and projected battleship “O”.

5. Complete specifications for the hull, machinery and armament of the 21,000 ton aircraft carrier Graf Zeppelin.

7.7.3 Bathyscaphes

During the period 1937–1960, Auguste Piccard (Swiss, 1884–1962), later assisted by his son Jacques Piccard (Swiss, 1922–2008), developed a series of bathyscaphes in order to carry people to extreme ocean depths, where the pressure would crush a normal submarine. See Fig. 7.133. In 1960 their *Trieste* bathyscaphe reached the deepest known part of the ocean, the floor of the Challenger Deep in the Mariana Trench, which is approximately 11 kilometers below the surface and has a pressure approximately 1100 times greater than sea-level atmospheric pressure. *Encyclopedia Britannica* explained [EB 2010]:

> bathyscaphe, navigable diving vessel developed by the Swiss educator and scientist Auguste Piccard (with assistance in later years from his son Jacques), designed to reach great depths in the ocean.
>
> The first bathyscaphe, the *FNRS 2*, built in Belgium between 1946 and 1948, was damaged during 1948 trials in the Cape Verde Islands. Substantially rebuilt and greatly improved, the vessel was renamed *FNRS 3* and carried out a series of descents under excellent conditions, including one of 4,000 m (13,000 feet) into the Atlantic off Dakar, Senegal, on Feb. 15, 1954. A second improved bathyscaphe, the *Trieste*, was launched on Aug. 1, 1953, and dived to 3,150 m (10,300 feet) in the same year. In 1958 the *Trieste* was acquired by the United States Navy, taken to California, and equipped with a new cabin designed to enable it to reach the seabed of the great oceanic trenches. Several successive descents were made into the Pacific by Jacques Piccard, and on Jan. 23, 1960, Piccard, accompanied by Lieutenant Don Walsh of the U.S. Navy, dived to a record 10,916 m (35,810 feet) in the Pacific’s Mariana Trench.

7.7.4 Rotor Ships

In 1852, Heinrich Gustav Magnus (Prussian, 1802–1870, p. 1484) described and analyzed what is now known as the Magnus effect, in which a spinning cylinder or sphere deflects incoming airflow toward one side, pushing the cylinder or sphere toward the other side. By harnessing this Magnus effect, Anton Flettner (German, 1885-1961) developed rotor ships that use spinning cylinders or rotors like sails for steering or propulsion (Fig. 7.134). Jakob Ackeret (Swiss, 1898–1981, p. 1696), Albert Betz (German, 1885–1968, p. 1665), Martin Kutta (German, 1867–1944, p. 844), and Ludwig Prandtl (German, 1875–1953, p. 1696) also played roles in analyzing the airflow around the spinning cylindrical rotors. Flettner demonstrated the first rotor ship, *Buckau*, in 1924, and a larger one, *Barbara*, in 1926.

Engineering professor Kurt Knobling described Flettner's rotor ship innovation [Hirschel et al. 2004, p. 299]:

> He aroused worldwide attention with his proposal to replace the sails of ships with upright standing perpendicular rotating cylinders, which produce, in the presence of an airflow (wind), thrust by utilizing the Magnus effect (discovered by Gustav Magnus, 1852). The Flettner experimental boats did, however, not achieve the success hoped for. In 1925, he founded his own company aiming at the application of the Flettner-rotor as wing replacement on large wind turbines. Albert Einstein appreciated Anton Flettner's sense for utilizing physical knowledge in practical applications in his publication "My View of Life" ("Mein Weltbild"), of 1934: "*Flettner saw Ludwig Prandtl's experiments (remark: experiments on rotating cylinders in an incoming air flow) and thought that one could use this installation to replace sails. Who knows, whether anybody else would have thought of that?*"

As shown in Fig. 7.134, rotors are still used on ships to supplement other methods and increase energy efficiency.

Flettner also created battlefield robots (p. 1208) and helicopters (p. 1824).

7.8 Other Creations in Mechanical Engineering

German-speaking creators also invented many other important devices in the field of mechanical engineering.[12] This section only includes a few illustrative examples:

7.8.1. Watches

7.8.2. Vacuum pumps and pressure valves

7.8.3. Bicycles

7.8.4. Polar planimeter

7.8.5. Liquid agitators and turbines

7.8.6. Gyroscopes and gyrocompasses

7.8.7. Sports shoes

7.8.1 Watches

Although stationary clocks had been around for centuries, Peter Henlein (German states, 1485–1542) invented the portable watch in 1505. Figure 7.135 shows the first Henlein watch from 1505 (upper right) and a very similar Henlein watch from 1530 (bottom). The science historian Felix Paturi described Henlein's innovations [Paturi 1998, p. 110]:

Bis über die Mitte des 15. Jh. hinaus mussten mechanische Uhren senkrecht stehen, da sie einen Schwerkraftantrieb durch Gewichte besaßen. Die Größe der Gewichte verbot zugleich den Bau kleiner mechanischer Uhren. Erst 1470 wurde der Federaufzug für mechanische Uhren bekannt.	Until beyond the middle of the 15th century, mechanical clocks had to stand vertically, as they had a gravity drive by weights. The size of the weights also prohibited the construction of small mechanical watches. It was not until 1470 that the spring winding mechanism for mechanical watches became known.
Der Nürnberger Mechaniker Peter Henlein (um 1485–1542) experimentiert als einer der Ersten mit kleinen Uhrfedern. Zugleich erkennt er, dass dieser Antrieb die Uhren lageunabhängig macht, weil die Schwerkraft keine Rolle mehr spielt. Bei seinen Versuchen gelingt es ihm, Uhren klein zu bauen, sodass sie in einförmige Dosen passen, die in der Tasche getragen werden können.	The Nuremberg mechanic Peter Henlein (around 1485–1542) was one of the first to experiment with small watch springs. At the same time, he realized that this drive made the watches independent of position, because gravity no longer played a role. In his experiments, he succeeded in making watches so small that they fit into standardized enclosures that could be carried in a pocket.

7.8.2 Vacuum Pumps and Pressure Valves

Otto von Guericke (German states, 1602–1686) invented the water barometer, manometer, and air pump. In 1650, he also created the "Magdeburg hemispheres" to demonstrate a vacuum; he pumped the air out of the space formed by two steel hemispheres, then demonstrated that two teams of horses could not pull the spheres apart (Fig. 7.136). *Encyclopedia Britannica* listed some of von Guericke's accomplishments [EB 2010]:

> Guericke was educated at the University of Leipzig and studied law at the University of Jena in 1621 and mathematics and mechanics at the University of Leyden in 1623. In 1631 he became an engineer in the army of Gustavus II Adolphus of Sweden, and from 1646 to 1681 he was *bürgermeister* (mayor) of Magdeburg and magistrate for Brandenburg.
>
> In 1650 Guericke invented the air pump, which he used to create a partial vacuum. His studies revealed that light travels through a vacuum but sound does not. In 1654, in a famous series of experiments that were performed before Emperor Ferdinand III at Regensburg, Guericke placed two copper bowls (Magdeburg hemispheres) together to form a hollow sphere about 35.5 (14 inches) in diameter. After he had removed the air from the sphere, horses were unable to pull the bowls apart, even though they were held together only by the air around them. Thus the tremendous force that air pressure exerts was first demonstrated.
>
> In 1663 he invented the first electric generator, which produced static electricity by applying friction against a revolving ball of sulfur. In 1672 he discovered that the electricity thus produced could cause the surface of the sulfur ball to glow; hence he became to first man to view electroluminescence. Guericke also studied astronomy and predicted that comets would return regularly from outer space.

Hermann Sprengel (German states, 1834–1906) invented the first pump for creating a high vacuum (<1/100,000,000 of normal atmospheric pressure), illustrated in Fig. 7.137.

As shown in Fig. 7.138, Hanns Hörbiger (Austrian, 1860–1931) invented the Hörbiger disc valve for high-pressure chemistry, compressors, blast furnaces, and other applications.[13]

7.8.3 Bicycles

In the 1650s, Hans Hautsch (German states, 1595–1670) and Stephan Farfler or Farffler (German states, 1633–1689) invented and demonstrated tricycles and quadracycles powered by a hand-cranked gearbox for use as wheelchairs by paraplegics. Farfler himself was a paraplegic or amputee who made extensive use of such vehicles (Fig. 7.139).

Karl von Drais (German states, 1785–1851, Fig. 7.140) invented a quadracycle with foot pedals in 1813, and then the first bicycle (without pedals) in 1817. Von Drais also created a paper music recorder in 1812 and the first keyboard typewriter in 1821 (p. 1300).[14] *1001 Inventions That Changed the World* explained the motivation for von Drais's quadracycle and bicycle inventions [Challoner 2009, p. 268]:

> [...F]ollowing some bad weather in 1812, the price of oats was climbing, and the German inventor Karl Drais (1785–1851) was looking for something to replace hungry horses. He designed a four-wheeled vehicle, powered by a servant sitting in the back pedaling, while the master steered from the front with a tiller. It did not catch on and Drais decided to focus instead on surveying equipment.
>
> After the 1815 volcanic eruption, even worse weather caused oat prices to climb higher still. The need for horseless transport was even more pressing, and so Drais tried again. He switched from four wheels to two and got rid of the pedals completely. What he invented in 1817 was called the draisine or the *draisienne*, depending on where you lived.

Philipp Moritz Fischer (German, 1812–1890) added pedals back to bicycles in 1853.[15] See Fig. 7.141.

7.8.4 Polar Planimeter

In 1854, Jakob Amsler-Laffon (Swiss, 1823–1912) invented the polar planimeter (Fig. 7.142). The *Complete Dictionary of Scientific Biography* explained its importance [https://www.encyclopedia.com/science/dictionaries-thesauruses-pictures-and-press-releases/amsler-later-amsler-laffon-jakob]:

> Until 1854 Amsler's interests lay in the area of mathematical physics; he published articles on magnetic distribution, the theory of heat conduction, and the theory of attraction. One result of his work was a generalization of Ivory's theorem on the attraction of ellipsoids and of Poisson's extension of that theorem. In 1854 Amsler turned his attention to precision mathematical instruments, and his research resulted in his major contribution to mathematics: the polar planimeter, a device for measuring areas enclosed by plane curves. Previous such instruments, most notably that of Oppikofer (1827), had been based on the Cartesian coordinate system and had combined bulkiness with high cost. Amsler eliminated these drawbacks by basing his planimeter on a polar coordinate system referred to a null circle as curvilinear axis. The instrument, described in "Ueber das Polarplanimeter" (1856), adapted easily to the determination of static and inertial moments and of the coefficients of Fourier series; it proved especially useful to shipbuilders and railroad engineers.
>
> To capitalize on his inspiration, Amsler established his own precision tools workshop in 1854. From 1857 on he devoted full time to the venture. At his death, the shop had produced 50,000 polar planimeters and 700 momentum planimeters.

7.8.5 Liquid Agitators and Turbines

In the 1760s, Gotthard Friedrich Stender (Baltic German, 1714–1796) and Jacob Christian Schäffer (German states, 1718–1790) built clothes washing machines with agitator blades and mechanical drives for multiple machines. See Fig. 7.143.

Viktor Kaplan (Austrian, 1876–1934) invented highly efficient turbines with blades of adjustable tilt for hydroelectric power (pp. 1499, 3757). His designs are still in use today. Oxford University's *Biographical Dictionary of Scientists* described Kaplan's innovation [Porter 1994, p. 378]:

> Kaplan published his first paper on turbines in 1908, writing about the Francis turbine and basing it on work that he had done for his doctorate at the Technische Hochschule in Vienna. In connection with this paper, he set up a propeller turbine for the lowest possible fall of water. In 1913 the first prototype of the turbine was completed. The Kaplan turbine was patented in 1920 as a water turbine with adjustable rotor-blades; the runner blades can be varied to match the correct angle for a given flow of water. [...]
>
> The Kaplan turbine in its traditional form has a vertical shaft, although one power-generator design uses a horizontal shaft and an alternator mounted in a 'nacelle' (metal shell) in the water flow. This is particularly suitable for lower-output machines operating on very low heads of water, in which an almost straight water passage is possible.

7.8.6 Gyroscopes and Gyrocompasses

Johann Bohnenberger (German, 1765–1831) invented the gyroscope in 1817, as illustrated in Fig. 7.145. By harnessing the basic principles of gyroscopes to create guidance systems, Hermann Anschütz-Kaempfe (German, 1872–1931) and Max Schuler (German, 1882–1972) developed increasingly accurate gyrocompasses from 1904 onward. In 1923, Schuler developed the principle of Schuler tuning that helps to ensure that gyrocompasses remain accurate regardless of where they are carried around the earth. *1001 Inventions That Changed the World* explained the importance of the development of gyrocompasses [Challoner 2009, p. 547]:

> Gyrocompasses have two great advantages over magnetic needle compasses: They point to the spin pole of Earth as opposed to the magnetic pole; and they are completely unaffected by the ferrous metal of a ship's hull or the magnetic fields produced by electrical currents running through nearby wires. Their main component is a motorized, fast-spinning, damped, gimballed wheel. When this wheel is not spinning exactly in the plane containing Earth's spin axis, an interaction between the angular momentum of the wheel and the angular momentum of Earth produces a restoring torque that pushes the wheel back into the true north-south orientation.
>
> A ship's gyrocompass is mounted in a complex set of gimbals that isolate the instrument from the ever-present pitching, yawing, and rolling. Aircraft gyrocompasses are even more complicated due to the higher velocity of the plane and the speedy changes in altitude during takeoff and landing.
>
> German scientist Hermann Anschütz-Kaempfe (1872–1931) started working on the device because he needed a compass to guide a submarine on a planned expedition underneath the north polar ice. In partnership with his cousin, Max Schuler, Anschütz-Kaempfe sold a prototype to the German Navy in 1908. Schuler found that if the pendulous suspension of the gyroscope had a period of eighty-four minutes (the period of a pendulum of length equal to Earth's radius), disturbances due to the ship's acceleration were canceled out.

7.8.7 Sports Shoes

Adolf Dassler (German, 1900–1978) designed sports shoes (ultimately called Adidas) from 1918 onward. First working with him and then in competition with him, his brother Rudolf Dassler (German, 1898–1974) designed sports shoes (ultimately called Puma) from 1924 onward [Karlsch et al. 2019; Rolf-Herbert Peters 2007]. See Fig. 7.146.

Chapter 8

Creators and Creations in Nuclear Science and Engineering

Ins Ewige wiederholen...
Keiner gönnt das Reich
Dem andern; dem gönnt's keiner,
der's mit Kraft erwarb
Und kräftig herrscht.
Denn jeder, der sein innres Selbst
Nicht zu regieren weiß,
regierte gar zu gern
Des Nachbars Willen,
eignem stolzem Sinn gemäß...
Hier aber ward ein großes Beispiel
durchgekämpft:
Wie sich Gewalt
Gewaltigerem entgegenstellt, [...]
Das wird sich messen.
Weiß die Welt doch, wem's gelang.
Wachfeuer glühen,
rote Flammen spendende,
Der Boden haucht
vergoßnen Blutes Widerschein, [...]
Der Zelten Trug verschwindet,
Feuer brennen blau.
Doch über mir!
welch unerwartet Meteor?
Es leuchtet und beleuchtet
körperlichen Ball.

It repeats eternally...
No one freely gives the realm
To another;
to the one whose power won it
And whose strength rules.
For everyone, who does not even know
How to govern his own inner self,
would all too gladly rule over
His neighbour's will,
prompted by his own proud mind...
But here a great example was
fought to the end,
How force battles
against a greater force, [...]
This is tested.
The world knows who won.
Bonfires glow,
sending out red flames:
The ground is soaked
with images of spilled blood, [...]
The illusion of dwellings vanishes;
the fires burn blue.
But overhead,
what sudden meteor is this?
It shines and illuminates
the whole world.

Johann von Goethe. 1832. *Faust Part Two.*
Act II. Klassische Walpurgisnacht. Erichtho.

A huge number of innovators and innovations in the field of nuclear science and engineering came from the predominantly German-speaking central European research world.[1] German-speaking contributions to early nuclear science are well documented and widely accepted, and include:

8.1. Nuclear diagnostics and therapeutics

8.2. Radiation detectors

8.3. Particle accelerators

8.4. Models of the atomic nucleus

8.5. Nuclear fission reactions

8.6. Nuclear fusion reactions

German-speaking contributions to specific engineering applications of that science are a much more complex topic, and are far less well known by the general public in the modern world. In fact, German-speaking scientists played decisive roles not just in the world's first nuclear engineering program, but in all three of the world's first nuclear engineering programs:

8.7. The World War II and postwar U.S./U.K. nuclear program

8.8. The wartime German nuclear program (For the full presentation and analysis of evidence that the wartime German nuclear program was much larger and more advanced than has been generally recognized, see Appendix D.)

8.9. The postwar Soviet nuclear program

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

There is significant evidence that German-speaking scientists and their technologies played critical roles in additional nuclear programs as well (in France, Israel, etc.), but for reasons of length this book will only focus on those earliest three programs. (Moreover, despite the loss of enormous numbers of nuclear scientists and resources to the United States, Soviet Union, United Kingdom, France, and other countries after the war, West Germany *still* had enough nuclear scientists and industry left to propose its own serious nuclear weapons program until that was terminated for political reasons [Kollert 2000].)

Some well-known aspects of nuclear science were discovered outside the German-speaking world.[2] Marie and Pierre Curie, as well as their daughter and son-in-law Irène and Frédéric Joliot-Curie, characterized several radioactive elements at their Paris laboratory. Ernest Rutherford pioneered the methods of experimental nuclear physics as he moved his lab from McGill University in Montreal to the University of Manchester to the University of Cambridge. Enrico Fermi conducted early nuclear physics experiments at his lab in Rome, before moving to the United States, where he played a key role in the Manhattan Project.

On the other hand, an enormous number of major early nuclear discoveries came from the German-speaking world, as illustrated by the examples in this chapter.[3]

8.1 Nuclear Diagnostics and Therapeutics

Creators from the German-speaking world developed the major methods of nuclear diagnostics and therapeutics that are still used today, including:

8.1.1. X-rays

8.1.2. Radioisotopes and isotope labeling

8.1.3. Nuclear magnetic resonance, or magnetic resonance imaging

8.1.1 X-Rays

In 1895, Wilhelm Röntgen (German, 1845–1923) discovered X-rays, which have often been called Röntgen rays ever since. Ludwig Zehnder (Swiss, 1854–1949, also known for the Mach-Zehnder interferometer—p. 1029) was making detailed whole-body X-ray photographs of humans by 1896; see Fig. 8.1. Of course, X-rays are still widely used for everything from medical exams and dental checkups to airport baggage screening and mechanical parts inspections.

Wilhelm Röntgen won the first Nobel Prize in Physics in 1901. At that first Nobel Prize ceremony, C. T. Odhner, President of the Royal Swedish Academy of Sciences, explained why the importance of Röntgen's work was already evident to the world just six years after his discovery [https://www.nobelprize.org/prizes/physics/1901/ceremony-speech/]:

---

[2] See for example: Beyer 1949; Cronin 2004; Curie 1938; Fermi 1950; Fermi 1987; L'Annunziata 2016; Reeves 2008; Segrè 1970; Weart 1979.

[3] See for example: Bethe 1991, 1997; Blatt and Weisskopf 1952; Brown and Lee 2006; Otto Hahn 1968; Irving 1967; L'Annunziata 2016; Nachmansohn 1979; Rife 1999; Schweber 2012; Sime 1996; Szanton 1992; Wigner 1967.

> The Academy awarded the Nobel Prize in Physics to Wilhelm Conrad Röntgen, Professor in the University of Munich, for the discovery with which his name is linked for all time: the discovery of the so-called Röntgen rays or, as he himself called them, X-rays. These are, as we know, a new form of energy and have received the name "rays" on account of their property of propagating themselves in straight lines as light does. The actual constitution of this radiation of energy is still unknown. Several of its characteristic properties have, however, been discovered first by Röntgen himself and then by other physicists who have directed their researches into this field. And there is no doubt that much success will be gained in physical science when this strange energy form is sufficiently investigated and its wide field thoroughly explored. Let us remind ourselves of but one of the properties which have been found in Röntgen rays; that which is the basis of the extensive use of X-rays in medical practice. Many bodies, just as they allow light to pass through them in varying degrees, behave likewise with X-rays, but with the difference that some which are totally impenetrable to light can easily be penetrated by X-rays, while other bodies stop them completely. Thus, for example, metals are impenetrable to them; wood, leather, cardboard and other materials are penetrable and this is also the case with the muscular tissues of animal organisms. Now, when a foreign body impenetrable to X-rays, e.g. a bullet or a needle, has entered these tissues its location can be determined by illuminating the appropriate part of the body with X-rays and taking a shadowgraph of it on a photographic plate, whereupon the impenetrable body is immediately detected. The importance of this for practical surgery, and how many operations have been made possible and facilitated by it is well known to all. If we add that in many cases severe skin diseases, e.g. lupus, have been successfully treated with Röntgen rays, we can say at once that Röntgen's discovery has already brought so much benefit to mankind that to reward it with the Nobel Prize fulfils the intention of the testator to a very high degree.

Leopold Freund (Austrian, 1868–1943) and Eduard Schiff (Austrian, 1849–1913) developed and employed radiation therapy from 1896 onward (Fig. 8.2). As shown in Fig. 8.3, Freund wrote the first medical textbook on radiation therapy in 1902 and published it in 1903 [Leopold Freund 1903]. Translations of the book in English and other languages were published in 1904, so Freund truly founded and shaped the field of radiation therapy worldwide. Freund also invented and successfully demonstrated the first chemical sunscreen, Antilux, in 1922 (p. 126).

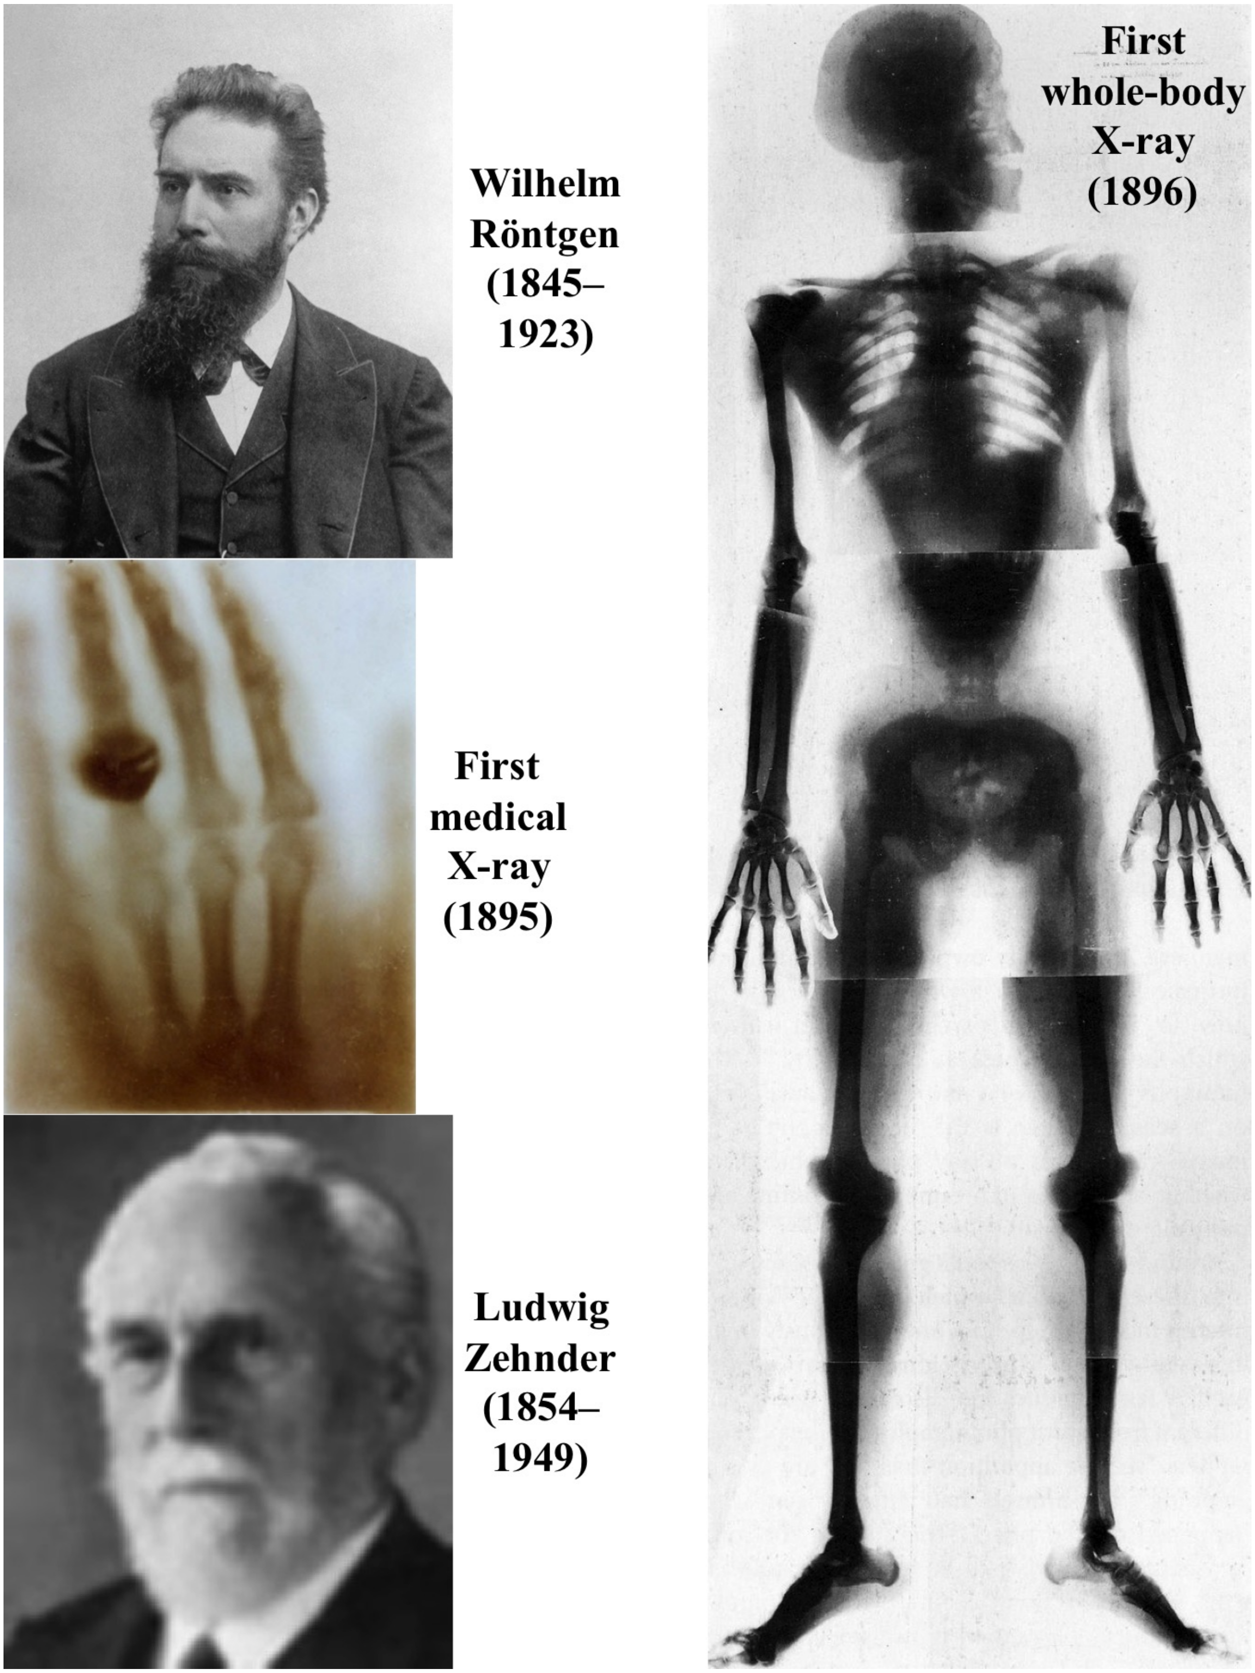
Radiologist H. Dieter Kogelnik wrote about the historical and scientific importance of Leopold Freund in that field [Kogelnik 1997]:

> There is an increasing acceptance and knowledge of the fact that the inauguration of radiotherapy as a new scientific speciality was performed by Leopold Freund 100 years ago. With a clear and logical rationale, Freund provided the first scientific proof of the biological effectiveness of X-rays on a 5-year-old patient and performed the world's first successful treatment with X-rays. Before Freund's historical experimental treatments, which started in Vienna on November 24th, 1896, there were several suggestions and attempts at the therapeutic use of X-rays, however none of these mostly one-of-a-kind attempts was successful, and there was no scientific proof of a therapeutic effectiveness of X-rays in these previous experiments.

Carl H. F. Müller (German, 1845–1912) began producing vacuum tubes in 1880 and X-ray tubes in 1896. His company and its researchers remained at the forefront of producing instruments for nuclear science until 1945. Advanced German X-ray tubes—and information on how to make them—were publicly heralded as important prizes that the United States obtained from Germany after World War II (pp. 423, 3958–3970).

During the period 1922–1924, Dirk Coster (Dutch, 1889–1950) developed X-ray spectroscopy, or methods to separate different wavelengths of X-rays and use them to make new discoveries. Using X-ray spectroscopy, Coster and George de Hevesy (Hungarian, 1885–1966) discovered hafnium in 1923 (p. 439).

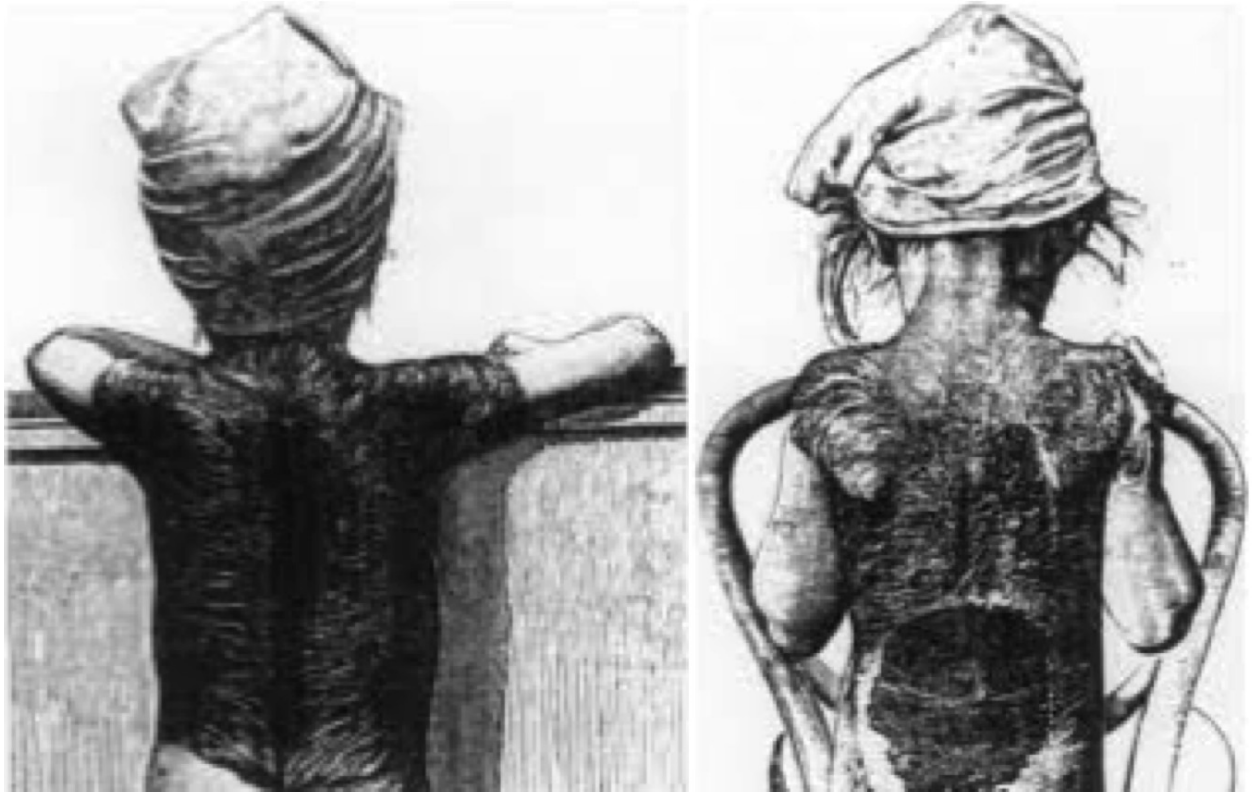
Two other especially noteworthy scientists who worked on the medical implications and applications of radiation were Nikolai Timoféeff-Ressovsky (Russian but worked in Germany 1925–1945, lived 1900–1981) and Karl Günter Zimmer (German, 1911–1988). Along with Max Delbrück, in 1935 they published a groundbreaking paper on the effects of radiation on genetic mutations and structure (p. 103). They also studied applications of radiation in neuroscience and other areas of biology. In 1945, Timoféeff-Ressovsky, Zimmer, and some of their colleagues moved to Russia and continued to study the biological effects of radiation as part of the German-speaking scientific community there.



Wilhelm Röntgen (1845–1923)
First medical X-ray (1895)
Ludwig Zehnder (1854–1949)
First whole-body X-ray (1896)

Figure 8.1: Wilhelm Röntgen discovered X-rays (often called Röntgen rays) and made the first human X-ray in 1895. Ludwig Zehnder made the first whole-body X-ray (a composite of nine X-ray films) in 1896.

Leopold Freund (1868–1943) **Eduard Schiff (1849–1913)**



Radiation therapy (1896)

Figure 8.2: Leopold Freund and Eduard Schiff invented radiation therapy. In 1896, they used X-rays to successfully treat a young girl with hairy growths on her entire back. They continued to develop and employ radiation therapy in the following years.

8.1.2 Radioisotopes and Isotope Labeling

Different isotopes of the same chemical element have the same number of protons and same number of electrons (and hence the same chemical properties), but different numbers of neutrons; that difference in neutron number creates a measurable mass difference, and also makes some isotopes radioactive. Isotopes that are radioactive can be extremely useful either for diagnostics or for radiation therapy. Even isotopes that are not radioactive can be detected by their mass differences and thus can be useful in chemistry and biology experiments.

Isotope labeling of chemical molecules was developed by George de Hevesy (Hungarian, 1885–1966), Hilde Levi (German, 1909–2003), Friedrich Paneth (Austrian, 1887–1958), and Rudolf Schoenheimer (German, 1898–1941); see Fig. 8.4. The ability to follow labeled molecules as they pass through chemical reactions, biological systems, and the environment revolutionized our understanding of chemistry, biology, and earth science. Radioisotope labeled molecules continue to be widely used for medical diagnostics and cancer therapeutics. De Hevesy won a Nobel Prize in Chemistry in 1943. Professor A. Westgren, member of the Nobel Committee for Chemistry, explained how extensive de Hevesy's research was [https://www.nobelprize.org/prizes/chemistry/1943/ceremony-speech/]:

> This discovery was made some ten years ago and the study of chemical processes by means of radioactive markers has since then been carried to such a point that it is now widely used in laboratories throughout the world. De Hevesy has remained the prime mover in this new field of activity and much first-class and important research has been carried out by him and his co-workers.
>
> Exceptionally valuable results have thus been obtained in biology. An isotope of radioactive phosphorus, which can be obtained by exposing sulphur to neutron radiation or ordinary phosphorus to radiation from nuclei of heavy hydrogen, has mostly been used. This radioactive phosphorus is sufficiently long-lasting for tests of this nature. It has a half-life of approximately 14.8 days. De Hevesy produced physiological solutions of sodium phosphate containing this marker and injected them into animals and humans. The distribution of the phosphorus was determined at certain intervals. A study of blood samples showed that the phosphorus thus introduced quickly left the blood. In human blood the radio-phosphorus content had fallen after only 2 hours to a mere 2% of its initial value. It diffuses into the extra-cellular body fluid and gradually changes places with the phosphorus atoms of the tissues, organs and skeleton. After some time it can even be found, though in very small quantities, in the enamel of the teeth. Exchanges small and slow as they may be, therefore occur between the outer hard parts of the teeth and the inner tissues of the bones and the lymph. Most of the phosphorus introduced, finds its way into the skeleton, muscles, liver and gastro-intestinal organs. Elimination of phosphorus from living organisms has also been studied by this method.
>
> Phosphorus is an extremely important element in biological processes. The knowledge of its functions in living organisms which has been acquired thanks to the use of radioactive markers is therefore of the very greatest interest. De Hevesy succeeded in detecting where and at what speed the various organic compounds of phosphorus are able to form and the paths which they take in the animal organism. In order to form from a phosphate which has been injected into the blood they must first penetrate into the cells. Acid-soluble compounds of phosphorus form rapidly, whereas phosphatides closely related to

> fatty substances are slower-forming. These latter form mainly in the liver, whence they are carried by the blood plasma to the places where they will be consumed. De Hevesy showed that the phosphatides of the chicken embryo are produced in the embryo itself and that they cannot be extracted from the egg yolk.
>
> De Hevesy also carried out several investigations with radioactive sodium and potassium. He studied how physiological saline containing radioactive sodium which was injected into a human subject first spread into the blood and then slowly penetrated into the cells; he also studied the manner in which it is excreted. After 24 hours the blood corpuscles had lost approximately half their sodium content.
>
> In addition to the above-mentioned markers, several other active isotopes, such as magnesium, sulphur, calcium, chlorine, manganese, iron, copper and zinc, have been used for this type of research. In the case of the lighter elements it has also been possible to use inactive isotopes such as heavy hydrogen, with an atomic weight of 2, nitrogen, with an atomic weight of 15, and oxygen, with an atomic weight of 18. It is of course less easy to determine the content of an inactive than of an active marker, but this can be done by determinations of density or mass-spectrographically. To determine the concentration of deuterium, or heavy hydrogen, which is twice as heavy as ordinary hydrogen, is a relatively easy matter. De Hevesy used deuterium as marker in many tests. He then noticed that a person who has drunk water containing heavy hydrogen excretes deuterium in the urine after only 26 minutes. Frogs and fishes swimming in water containing deuterium absorb it and, after about 4 hours, are in equilibrium with the medium as far as the deuterium is concerned. Heavy nitrogen and heavy oxygen have also been used in many investigations.

Technetium, which is especially useful for radioisotope labeling due to its short half-life and readily detectable gamma rays, was discovered in 1925 by Otto Berg (German, 1873–1939), Walter Noddack (German, 1893–1960), and Ida Tacke Noddack (German, 1896–1978); see p. 436.

Similarly, Berta Karlik (Austrian, 1904–1990), shown in Fig. 8.5, worked out the radioactive decay process that produces astatine, a previously undiscovered element (number 85) and ultimately an important radioactive treatment for cancer.[4]

Ulrich Henschke (German, 1914–1980) invented and commercialized a variety of brachytherapy methods for treating cancer with very localized radioactive sources or tightly targeted radiation beams. Henschke also made important contributions in several other unrelated fields. See p. 2514 for more information.

German-speaking scientists also led the rest of the world in research on all other aspects of cancer causes, prevention, and treatment (p. 113).

---

[4] As an aside, for this period in history, women appear to have been remarkably numerous and successful in the greater German-speaking nuclear physics community. Hilde Levi, Ida Tacke Noddack, and Berta Karlik have already been mentioned, and Marietta Blau, Erika Cremer, Klara Döpel, Maria Goeppert Mayer, and Lise Meitner are discussed in later sections. While these were some of the most prominent women in the nuclear physics community, there were a number of others as well. Unfortunately, even these most prominent women have been largely forgotten by history, except for Meitner, who has been the subject of two major biographies in recent decades [Rife 1999; Sime 1996]. It would be interesting to study whether other scientific fields had similarly large populations of female scientists who have been neglected by historians, or if there were certain factors that allowed women to go further in nuclear physics than in many other fields of science and engineering at that time. (Of course, Marie Curie and her daughter Irène Joliot-Curie are well-known examples of women who were successful in nuclear physics outside the

8.1.3 Nuclear Magnetic Resonance (NMR)/Magnetic Resonance Imaging (MRI)

Nuclear magnetic resonance (NMR), also called magnetic resonance imaging (MRI), does not involve radiation or radioactivity, but rather uses intense magnetic fields to identify different types of atomic nuclei. Thus it can be used to identify various types of atoms and their relative locations within a chemical molecule, or to track the locations of oxygen or other atoms being used within the human body.

Pieter Zeeman (Dutch, 1865–1943) and Hendrik Lorentz (Dutch, 1853–1928) discovered that applied magnetic fields shift the energy levels of electrons orbiting in atoms, and therefore the frequencies of electromagnetic waves that they absorb and emit. For demonstrating and explaining what is now known as the Zeeman effect, both Zeeman and Lorentz won the Nobel Prize in Physics in 1902 (p. 891).

Beginning in the 1930s, I. I. Rabi (Austro-Hungarian by birth and educated in the German-speaking scientific community, 1898–1988) and Felix Bloch (Swiss, 1905–1983) demonstrated that sufficiently strong magnetic fields could create a Zeeman-type effect not just of the electrons orbiting in an atom, but of the nucleus at the center of an atom (Fig. 8.6). Under such conditions, the atomic nuclei of different chemical elements, or different isotopes of the same element, have slightly different magnetic signatures that can be detected using the fields.

For laying the foundations for NMR/MRI, Rabi won the Nobel Prize in Physics in 1944. At the award ceremony, Professor E. Hulthén of the Nobel Committee for Physics praised the cleverness and utility of Rabi's accomplishments [https://www.nobelprize.org/prizes/physics/1944/ceremony-speech/]:

> Let us now for a moment touch upon Rabi's achievements in this field. Returning to the essential point of the problem, let us put the question: How does the atom react to the magnetic field? According to a theorem stated by the English mathematician Larmor, this influence may be ascribed to a relatively slow precession movement on the part of the electron and the atomic nucleus around the field direction—a gyromagnetic effect most closely recalling the gyroscopic movement performed by a top when it spins around the vertical line. If the strength of the magnetic field is known, the magnetic factor of the electron and of the atomic nucleus can also be estimated by this means, provided that we can observe and measure these precessional frequencies. Rabi solved the problem in a manner as simple as it was brilliant. Within the magnetic field was inserted a loop of wire, attached to an oscillating circuit the frequency of which could be varied in the same manner as we tune in our radio receiving set to a given wavelength. Now, when the atomic beam passes through the magnetic field, the atoms are only influenced on condition that they precess in time with the electric current in the oscillating circuit. This influence might perhaps be described graphically: the nucleus performs a vault (salto)—the technical term for which is a "quantum jump"—thereby landing in another positional direction to the field. But this means that the atom has lost all chance of reaching the detector and of being registered by it. The effect of these quantum jumps is observable by the fact that the detector registers a marked resonance minimum, the frequency position of the registration being determined with the extraordinary precision achievable with the radio frequency gauge. By this method Rabi has literally established

---

German-speaking world.)

> radio relations with the most subtile particles of matter, with the world of the electron and of the atomic nucleus.

Felix Bloch won the Nobel Prize in Physics in 1952 for his own role in the development of NMR/MRI and related techniques. Professor E. Hulthén addressed him at the award ceremony [https://www.nobelprize.org/prizes/physics/1952/ceremony-speech/]:

> Professor Bloch. It would be difficult in the few minutes at my disposal to try to give the main features of the nuclear induction method for which you have been awarded your Nobel Prize. It would be still more difficult for me to give an exhaustive account of the ways that led you to this invention.
>
> You began your career as a theoretical physicist, well-known for your fundamental contributions to the theory of metals.
>
> When, quite unexpectedly, you went over to experimental research, this must have been, I feel, with deliberation and assurance. For you had in your kitbag a tool of extraordinary value, the method for the magnetic polarization of a beam of neutrons. The inestimable value of possessing a good idea, of indefatigably testing and perfecting it, is best illustrated by your precision-measurements of the magnetic moment of the neutron, one of the most difficult and at the same time most important tasks in nuclear physics.
>
> But ideas give birth to new ideas, and it was, as I understand, in this way that you hit upon the excellent notion of eliminating the difficult absolute determination of the magnetic field by a direct measurement of the neutron moment in units of the proton cycle (the nuclear magneton). According to your own account it was this solution which finally led you to the nuclear induction method.

Nicolaas Bloembergen (Dutch, 1920–2017, Fig. 6.63) was one of the major developers of early laboratory systems for NMR analysis. He won the Nobel Prize in Physics in 1981 for some of his other research on lasers. See p. 1033 for more information.

NMR/MRI was further developed by a number of scientists from the 1950s to the 1970s (including the American chemist Paul Lauterbur and the British physicist Peter Mansfield) and is now widely used for medical diagnostics and chemical analysis.

Richard Ernst (Swiss, 1933–, p. 607) developed NMR spectroscopy methods that are useful for studying chemical molecules and biological systems. For that work, he won the Nobel Prize in Chemistry in 1991. See p. 596 for more information.

Kurt Wüthrich (Swiss, 1938–, p. 614) developed methods to use NMR to study large molecules. For that innovation, he won the Nobel Prize in Chemistry in 2002 (p. 604).

8.2 Radiation Detectors

German-speaking scientists developed the major types of radiation detectors that are still widely used today, including electrical methods of detection (Section 8.2.1), optical methods of detection (Section 8.2.2), and more advanced methods such as Mössbauer spectroscopy (Section 8.2.3).

8.2.1 Electrical Detection of Radiation

German-speaking creators invented electrical methods of detecting radiation. Hans Geiger (German, 1882–1945) and Walther Müller (German, 1905–1979) developed Geiger counters or Geiger-Müller tubes between 1908 and 1928, while Heinrich Greinacher (Swiss, 1880–1974) developed similar proportional or spark counters in 1920. See Fig. 8.7.

Marc Shampo and his scientific colleagues gave an overview of Geiger's contributions [Shampo et al. 2011]:

> The German physicist Hans Wilhelm Geiger is best known as the inventor of the Geiger counter to measure radiation. In 1908, Geiger introduced the first successful detector of individual alpha particles. Later versions of this counter were able to count beta particles and other ionizing radiation. The introduction in July 1928 of the Geiger-Müller counter marked the introduction of modern electrical devices into radiation research. [...]
>
> In 1925, Geiger accepted his first teaching position, which was at the University of Kiel, Germany. Here, he and Walther Müller improved the sensitivity, performance, and durability of the counter, and it became known as the "Geiger-Müller counter." It could detect not only alpha particles but also beta particles (electrons) and ionizing photons. The counter was essentially in the same form as the modern counter.
>
> In 1929, Geiger moved to the University of Tübingen (Germany), where he was named professor of physics and director of research at the Institute of Physics. In 1929, while at the Institute, Geiger made his first observations of a cosmic-ray shower. Geiger continued to investigate cosmic rays, artificial radioactivity, and nuclear fission after accepting a position in 1936 at the Technische Hochschule in Berlin, a position he held until his death. In 1937, with Otto Zeiller, Geiger used the counter to measure a cosmic-ray shower.

Walther Bothe (German, 1891–1957, photo on p. 1611) developed methods of detecting a variety of different types of radiation, including alpha particles in 1927, cosmic rays in 1929, and neutrons in 1930. For this work, he won the Nobel Prize in Physics in 1954. Professor I. Waller, a member of the Nobel Committee for Physics, described Bothe's accomplishments [https://www.nobelprize.org/prizes/physics/1954/ceremony-speech/]:

> Professor Walther Bothe, who shares this year's Nobel Prize with Professor Born, began his scientific activity as a theoretical physicist.
>
> The work for which he has now been rewarded with the Nobel Prize was carried out by him in Berlin actually as an experimental physicist. These labours were based on a new use of counter tubes. A counter tube has the property of transmitting an electric current when a charged particle, e.g. an electron, passes through it; and also, with special contrivances, when a light particle collides with it. Bothe's idea was to use two counter tubes in such a manner that the two tubes would only register simultaneous

> collisions. Such coincidences can only come from two particles emitted in the same elemental process, or from a particle which has travelled through both tubes at high velocity so that the time it takes for the particle's passing from one tube to the other can be neglected.
>
> Bothe used this coincidence method in 1925 and also with improved apparatus about ten years later in order to decide whether the energy rule as well as its complement, the so-called impulse rule, is valid for every collision between a light particle and an electron—as Einstein and Compton assumed—or whether those rules are valid only on average for a large number of collisions—as Bohr and his collaborators had inferred. By investigating light particles and electrons by the coincidence method, Bothe and his co-workers were able to show convincingly that the rules mentioned are valid for every individual collision. This result was of great significance in principle. The coincidence method has been widely used in the study of cosmic radiation and is one of the most important experimental aids in the investigation of cosmic radiation. This method was first used in this way by Bothe when he was working with Kolhörster who had already given important contributions in the field of cosmic radiation. Bothe and Kolhörster used the coincidence method to pick out those particles in the cosmic radiation which had travelled through two counter tubes. The absorption of cosmic radiation into various materials was determined by placing layers of these substances between the tubes and studying the corresponding reduction in the number of coincidences. It was found that these particles are absorbed at about the same extent as the total cosmic radiation. From the experiments the particularly important result was obtained, that at sea level, cosmic radiation consists in the main of particles of very high penetration.
>
> Bothe and other researchers later improved the coincidence method and extended its field of application. This method has now become one of the most important aids in the study of both nuclear reactions and cosmic radiation.
>
> By many other discoveries and penetrating investigations also, Bothe has enriched our knowledge in these fields in very great measure and has provided an important stimulus to other researchers.

For more information on the contributions of the German-speaking world to the detection and analysis of cosmic rays, see p. 804.

8.2.2 Optical Detection of Radiation

German-speaking scientists also created the major optical methods of detecting radiation (Fig. 8.8).

As already described, Wilhelm Röntgen and Ludwig Zehnder developed X-ray photography in 1895 and 1896 (p. 1508).

Marietta Blau (Austrian, 1894–1970) demonstrated that photographic film could also be used to make practical particle detectors during the period 1927–1937.

Hartmut Kallmann (German, 1896–1978) created organic scintillator particle detectors that emitted light when radiation passed through them.

Karl Przibram (Austrian, 1878–1973) developed inorganic scintillator detectors with that same property.

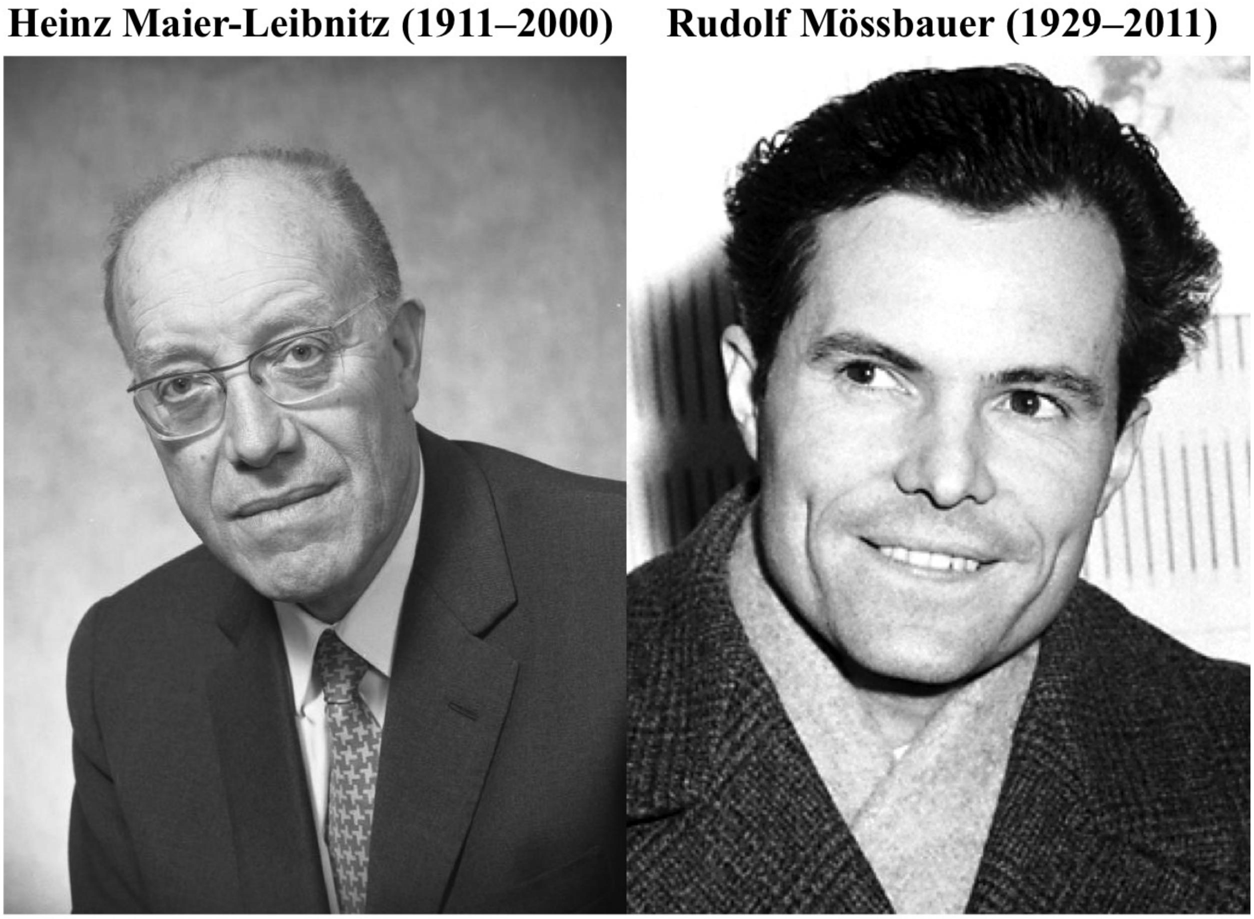
8.2.3 Mössbauer Spectroscopy

Following the suggestions of his doctoral thesis advisor Heinz Maier-Leibnitz (German, 1911–2000), during the period 1953–1958 Rudolf Mössbauer (German, 1929–2011) developed recoilless nuclear resonance absorption, which became known as the Mössbauer effect or Mössbauer spectroscopy (Fig. 8.9). Mössbauer won the Nobel Prize in Physics in 1961. Professor I. Waller of the Nobel Committee for Physics described the significance of this work [https://www.nobelprize.org/prizes/physics/1961/ceremony-speech/]:

> Professor Rudolf Mössbauer's investigations concern the emission and absorption of gamma radiation by the atomic nuclei. This radiation is of the same kind as the light and the radio waves. It is well known that incoming radio waves can be received only if the receiver is tuned to the same frequency as the sender. Resonance is then taking place. It has since long been tried to observe the corresponding phenomenon for nuclei, where it is called "resonance absorption". The method was to let gamma radiation from some kind of nuclei act upon other nuclei of exactly the same kind. There is however a certain difficulty connected with this experiment. The gamma radiation can be considered as made up of particles. When emitting a gamma particle the atom receives a recoil whereby the energy and therefore also the frequency of the gamma radiation is decreased. The same phenomenon occurs when the gamma particle is absorbed in the receiving nucleus. The resonance will be completely destroyed if the frequency change is not compensated for, as had been done already before Mössbauer's work. Mössbauer discovered experimentally and showed also theoretically that for atoms bound in a solid, an appreciable part of the radiation can be emitted without frequency change whereby the resonance absorption can be studied directly. This discovery was published by Mössbauer in 1958. Because of the very small width of the gamma lines the resonance is very sharp and can, as Mössbauer found, be influenced and finally inhibited by the Doppler effect if the source or the absorber for the gamma radiation is moved. The velocities required depend upon the sharpness of the gamma line and can be as small as some millimeters per hour.
>
> Mössbauer's discovery has been received with considerable interest. Research on the Mössbauer effect has been started at a great number of places. It has thereby been possible to verify in the laboratory, fundamental consequences of Einstein's theory of relativity. Other important applications depend on the separation and displacement of nuclear energy levels which occur in solids because of the influence of the surroundings. Many phenomena of this kind can in spite of their smallness be studied by the Mössbauer effect. It has been possible in this way to get most important information on the properties of solids.
>
> Mössbauer made his discovery when he investigated the resonance absorption on the suggestion of Professor Maier-Leibnitz in München. He found then some unexpected results which he investigated systematically and was thereby led to his discovery. [...]
>
> Professor Mössbauer. While doing research for your doctor's thesis you have discovered an unexpected effect which now bears your name. You have explained this effect experimentally and theoretically, and thereby created a device which is of fundamental importance in numerous realms of physics, and which is nowadays being investigated and put to use in a large number of physical laboratories. By your discovery it has become possible to examine precisely, numerous important phenomena formerly beyond or at the limit of attainable accuracy of measurement.



Heinz Maier-Leibnitz (1911–2000)
Rudolf Mössbauer (1929–2011)

Kernresonanzfluoreszenz von Gammastrahlung in Ir^{191}

Von

RUDOLF L. MÖSSBAUER *

Die Kernresonanzabsorption der dem Zerfall von Os^{191} folgenden 129 keV-Gammastrahlung in Ir^{191} wird untersucht. Der Wirkungsquerschnitt für die Resonanzabsorption wird als Funktion der Temperaturen von Quelle und Absorber im Temperaturbereich $90° \mathrm{K} < T < 370° \mathrm{K}$ gemessen. Die Lebenszeit τ_γ des 129 keV-Niveaus in Ir^{191} ergibt sich zu $(3{,}6^{+1{,}3}_{-0{,}8})\, 10^{-10}$ sec. Der Absorptionsquerschnitt zeigt bei tiefen Temperaturen einen starken Anstieg als Folge der Kristallbindung der Absorber- und Präparatsubstanzen. Die Theorie von LAMB über die Resonanzabsorption langsamer Neutronen in Kristallen wird auf die Kernresonanzabsorption von Gammastrahlung übertragen. Bei tiefen Temperaturen ergibt sich eine starke Abhängigkeit des Wirkungsquerschnittes für die Kernabsorption von der Frequenzverteilung im Schwingungsspektrum des Festkörpers.

Figure 8.9: Following the suggestions of Heinz Maier-Leibnitz, Rudolf Mössbauer developed recoilless nuclear resonance absorption, or Mössbauer spectroscopy.

8.3 Particle Accelerators and Ion Traps

Both particle accelerators and ion traps are important scientific tools for studying the fundamental physical properties of ions and other particles under different conditions:

> Particle accelerators (Section 8.3.1) are designed to increase the kinetic energy of particles as much as possible.
>
> Ion traps (Section 8.3.2) are intended to reduce the energy of particles as much as possible, in order to hold them relatively still for measurements.

8.3.1 Particle Accelerators

Although it is not widely known, German-speaking scientists invented particle accelerators in the 1920s and did an enormous amount of work before, during, and after World War II to develop them for various applications [Dippel 1992; Pancheri 2022; Sørheim 2020; Waloschek 2004, 2007, 2012; Burghard Weiss 1996].

Rolf Wideröe (Norwegian but studied and worked in Germany, 1902–1996) designed the first particle accelerators in 1923 and spent decades developing and building particle accelerators. See Fig. 8.10.

Max Steenbeck (German, 1904–1981, Fig. 8.11) began developing particle accelerators in 1927 and invented the first practical betatron (circular particle accelerator for electrons) in 1935.

Many other German-speaking scientists also developed and tested particle accelerators, including:

Manfred von Ardenne (German, 1907–1997)

Otto Baier (German?, 19??–19??)

Walther Bothe (German, 1891–1957)

Walter Dällenbach (Swiss, 1892–1990)

K. Fink (German?, 19??–19??)

Siegfried Flügge (German, 1912–1997)

Richard Gans (German, 1880–1954)

Rudolf Kollath (German, 1900–1978)

Helmuth Kulenkampff (German, 1895–1971)

H. Lange (German?, 19??–19??)

H. Salow (German?, 19??–19??)

Ernst Schiebold (German, 1894–1963)

Heinz Schmellenmeier (German, 1909–1994)

W. Schmitz (German?, 19??–19??)

Gerhard Schumann (German, 1911–19??)

Bruno Touschek (Austrian, 1921–1978)

A. Weckesser (German?, 19??–19??)

W. Wiebe (German?, 19??–19??)

In the German-speaking world, work on particle accelerators focused on at least four different but overlapping areas:

- Developing particle accelerator technology itself, including reaching higher and higher energies and numbers of particles in the beam.
- Using particle accelerators to answer fundamental questions in nuclear physics and other aspects of physics.
- Electronuclear breeding of weapons-grade fission fuel, and other applications relevant to developing nuclear weapons and nuclear reactors (see pp. 3954–4022, 4504–4510, and 5133–5134).
- Directed energy weapons (Section C.1). Many different versions of such weapons were under development during the war; they would have fired a beam of high-energy electrons and/or ions, or in some cases they would have harnessed the energy from those charged particles to produce an intense beam of X-rays, a burst of high-energy neutrons, or other forms of radiation. If some of the reports available in archives are correct, at least some of these weapons apparently reached the stage of successful tests against laboratory animals or solid targets.

In the 1930s, the U.S. physicists Ernest Lawrence and Donald Kerst discovered the early accelerator designs and writings of Rolf Wideröe and Max Steenbeck, copied them, and attained far greater fame than Wideröe and Steenbeck as the "inventors" of particle accelerators.

By the end of World War II, a number of advanced particle accelerators of various types had been built in the German-speaking world. The accelerators were seized and closely studied by different Allied countries after the war.

For more information on particle accelerators, see Section C.1 and pp. 3954–4022, 4504–4510, and 5133–5134. Much more archival research should be conducted to unearth new information on the development of particle accelerators in the German-speaking world, in order to determine exactly how far it progressed and how much it influenced programs in other countries.

I. Einleitung.

Schwierigkeiten in der Beherrschung hoher Spannungen.

Bekanntlich liegen alle Schwierigkeiten bei der Herstellung hoher Spannungen in der Beherrschung der elektrostatischen Felder. Alle technischen Isoliermaterialien haben eine begrenzte Isolierfähigkeit, bei einer gewissen Feldstärke schlagen sie durch und werden leitend. Die Höhe der erzeugten Spannung wird deswegen hauptsächlich durch die stark zunehmenden Dimensionen der Isolierung begrenzt.

Es besteht nun aber die Möglichkeit, diese Grenze der erzeugten Spannungen wesentlich zu erhöhen, indem man elektrostatische Felder weitgehend vermeidet und die Hochtransformierung mit Hilfe schnellbewegten Elektronen und Ionen vornimmt.

Potentielle und kinetische Spannungen.

Wenn sich elektrische Ladungen durch ein elektrisches Feld bewegen, speichern sie einen Teil der Feldenergie als kinetische Energie auf. Für die kinetische Energie gilt das allgemeine Gesetz, daß sie immer mit der potentiellen Energie verknüpft ist, im Entstehen und im Verschwinden.

Entsprechend dieser Tatsache erscheint es deswegen auch zweckmäßig, von der Spannung einer bewegten Ladung zu reden. Die Ladung erhält dann (in Analogie zu den Energiebegriffen) diese kinetische Spannung, wenn sie durch eine entsprechende potentielle Spannung gefallen ist.

Zwei Wege der Spannungserzeugung.

Bei der Herstellung hoher potentieller Spannungen ist man hauptsächlich zwei Wege gegangen.

Herrn
Professor Dr. W. Gerlach,

(13b) München 22
Ludwigstrasse 17

21/XII Wz.

Sehr geehrter Herr Professor,

wir haben bei unseren Arbeiten eine Beobachtung gemacht, die ich Ihnen möglichst schnell berichten möchte:

Während des letzten Monats haben wir mit ziemlich starken Strahlintensitäten gearbeitet. Während dieser Zeit habe ich, nach unseren bisherigen Messungen gerechnet, wohl einige r bekommen (Dr.Kollath etwas mehr). Diese Dosen sollten viel zu klein sein, um biologische Wirkungen hervorzurufen.

Bei der letzten Blutuntersuchung zeigten sich indessen bei mir deutliche struktuelle Veränderungen der Leucocyten. Dr.med.Kruse (Krankenhaus St.Georg) hat uns untersucht und verfolgt den weiteren Verlauf dieser Erscheinungen.

Die Erscheinung kann nur dadurch erklärt werden:

1) Daß unsere Meßinstrumente doch zu wenig angeben (überschlägige Berechnungen ergeben den Faktor 3 zu wenig)
2) Daß unsere Strahlung wesentlich stärkere biologische Wirkungen haben muß, als man annehmen sollte.

Wir bitten Sie, dies Erscheinungen den anderen mit ähnlichen Geräten arbeitenden Herren mitzuteilen, um Schäden durch Unvorsichtigkeiten zu vermeiden. Wir selbst werden sofort Maßnahmen zur Herabsetzung der Strahlengefahren vornehmen.

Mit freundlichen Grüßen

R. Wideröe

P.S. Wir erwarten in den nächsten Tagen den Besuch von Prof.Dänzer und Gentner, die verschiedene Fragen über die Elektronenschleudern mit uns besprechen wollen.

Siemens-Schuckertwerke Akt.-Ges. in Berlin-Siemensstadt*)

Vorrichtung zur Erzeugung von Elektronen hoher Energie durch das elektrische Wirbelfeld eines sich zeitlich ändernden magnetischen Hauptfeldes

Patentiert im Deutschen Reiche vom 7. März 1935 ab
Patenterteilung bekanntgemacht am 17. Oktober 1940

Der Erfindung liegt die Aufgabe zugrunde, mit möglichst einfachen technischen Mitteln, vor allen Dingen ohne Anwendung hoher Spannungen, Elektronenstrahlen hoher Energie, beispielsweise Strahlen mit einer Geschwindigkeit von mehreren Millionen Volt zu erzeugen.

Es ist vorgeschlagen worden, zu diesem Zweck ein magnetisches Wechselfeld zu verwenden, durch das ein elektrisches Wirbelfeld erzeugt wird, welches dem Elektron die notwendige Geschwindigkeit erteilt. Die Anordnung ist dabei so getroffen, daß die Elektronenbahn das magnetische Feld umschließt wie die Windungen der Sekundärwicklung eines Transformators den Transformatorkern und damit den diesen Kern durchsetzenden Fluß.

Bei einer bekannten Anordnung dieser Art umschließt ein ringförmiges hochevakuiertes Entladungsgefäß den Kern eines dreischenkligen Transformators, dessen mittlerer Kern eine an technische Wechselspannung üblicher Spannung und Frequenz angeschlossene Erregerwicklung trägt. In dem Entladungsgefäß ist eine Glühkathode angeordnet, welche die für die Strahlung notwendigen Elektronen aussendet. Außer dem Wechselfeld wirkt auf die Elektronen noch ein zusätzliches, von Dauermagneten erzeugtes Magnetfeld, welches dazu dienen soll, die um den Transformatorkern kreisenden Elektronen in einer bestimmten, durch das Entladungsgefäß gegebenen Ebene zu halten, d. h. zu verhindern, daß die Elektronen an irgendeiner Stelle auf die Gefäßwandung auftreffen.

Es ist auch schon vorgeschlagen worden, zur Beschleunigung und Führung der Elektronen bei einer Anordnung zur Herstellung von Röntgenstrahlen ein Magnetfeld zu verwenden, welches von der Mitte nach dem Rande hin abfällt. Dabei ist der Körper, der durch das Auftreffen schnell fliegender Elektronen zum Aussenden von Röntgenstrahlen angeregt werden soll, in der Mitte des Magnetfeldes angeordnet.

Diese bekannten bzw. vorgeschlagenen Anordnungen sind zwar im Prinzip brauchbar, doch geben sie entweder eine verhältnismäßig geringe Ausbeute an schnellen Elektronen, oder sie sind für den vorliegenden Zweck der Erzeugung sehr rascher Elektronen nicht besonders geeignet. Um praktisch wirklich brauchbare Ergebnisse zu erzielen, muß man

8.3.2 Ion Traps

As shown in Fig. 8.12, Frans Penning (Dutch, 1894–1953), Wolfgang Paul (German, 1913–1993, not to be confused with the theoretical physicist Wolfgang Pauli), and Hans Dehmelt (German, 1922–2017) developed electromagnetic mass spectrometers and electromagnetic ion traps (Penning traps) to confine small numbers of ions of different elements for direct measurements. For that work, Paul and Dehmelt won the Nobel Prize in Physics in 1989. Professor Ingvar Lindgren of the Royal Swedish Academy of Sciences explained the importance of their innovations [https://www.nobelprize.org/prizes/physics/1989/ceremony-speech/]:

> An atom has certain fixed energy levels, and transition between these levels can take place by means of emission or absorption of electromagnetic radiation, such as light. Transition between closely spaced levels can be induced by means of radio-frequency radiation, and this forms the basis for so-called resonance methods. The first method of this kind was introduced by Professor I. Rabi in 1937, and the same basic idea underlies the resonance methods developed later, such as nuclear magnetic resonance (NMR), electron-spin resonance (ESR) and optical pumping. [...]
>
> The dream of the spectroscopist is to be able to study a single atom or ion under constant conditions for a long period of time. In recent years, this dream has to a large extent been realized. The basic tool is here the ion trap, which was introduced in the 1950s by another of this year's laureates, Wolfgang Paul in Bonn. His technique was further refined by the third laureate, Hans Dehmelt, and his co-workers in Seattle into what is now known as ion-trap spectroscopy.
>
> Dehmelt and his associates used this spectroscopy primarily for studying electrons, and in 1973 they succeeded for the first time in observing a single electron in an ion trap, and in confining it there for weeks and months. One property of the electron, its magnetic moment, was measured to 12 digits, 11 of which have later been verified theoretically. This represents a most stringent test of the atomic theory known as quantum electrodynamics (QED).
>
> In a similar way, Dehmelt and others were later able to trap and study a single ion, which represents a true landmark in the history of spectroscopy. The technique is now being used in development of improved atomic clocks, in particular at the National Institute for Standards and Technology (formerly the National Bureau of Standards) in Boulder, Colorado.

8.4 Models of the Atomic Nucleus

Scientists from the German-speaking world discovered all three of the building blocks of atoms: electrons, protons, and neutrons (Section 5.2.3).

German-speaking scientists were also directly responsible for developing detailed mathematical models of the behavior of the protons and neutrons in the atomic nucleus. These models are necessary for predicting various types of radioactive decays and nuclear reactions [Karen Johnson 2004; Shaviv 2012]. See Figs. 8.13–8.16.

For simplicity, these nuclear models may be divided into two broad categories:

> The liquid drop model (Section 8.4.1) essentially treats the nucleus like a continuous drop of liquid rather than a collection of individual particles, although it does incorporate quantum corrections for interactions between the individual particles.
>
> The shell model (Section 8.4.2) refines the liquid drop model by also considering the different energy levels or shells that particles within the nucleus can occupy, and the maximum allowable numbers of particles per shell.

8.4.1 Liquid Drop Model

Serious study of the internal structure of the nucleus arguably began in 1913, when Kasimir Fajans (Polish, 1887–1975) first worked out the radioactive displacement law of how alpha and beta radioactive decay transform one element into another.

In 1935, Carl Friedrich von Weizsäcker (German, 1912–2007) published a remarkably comprehensive and detailed mathematical model of the structure and energy levels of the nucleus (Figs. 8.15–8.16). It is still widely used today to accurately predict nuclear decays and reactions, and is known as the von Weizsäcker semi-empirical mass formula. Hans Bethe (German, 1906–2005) modified and utilized von Weizsäcker's formula in his own research. George Stetter (Austrian, 1895–1988) also conducted very early and very meticulous comparisons of theoretical and experimental results of nuclear energy levels and masses (Fig. 8.15).

George Gamow (Russian but educated and worked in Germany, lived 1904–1968) applied quantum physics to nuclear models in order to explain the rates of alpha decay [Gamow 1932].

Victor Weisskopf (Austrian, 1908–2002) and John (Johann) M. Blatt (Austrian, 1921–1990) produced what was at the time (and arguably remains, apart from coverage of the shell model) the most comprehensive theoretical compilation of information on nuclear structure [Blatt and Weisskopf 1952].

Die Massenbestimmung von Atomtrümmern aus Aluminium, Kohlenstoff, Bor und Eisen.

Von **Georg Stetter** in Wien.

Mit 6 Abbildungen. (Eingegangen am 22. März 1927.)

Mit dem früher beschriebenen Massenspektroskop für schnelle und seltene Korpuskularstrahlen werden nach entsprechender Weiterbildung der Methodik Spektralkurven der Sekundärteilchen aus den Elementen Al, C, B und Fe aufgenommen und außer α^{++}- und α^{+}-Teilchen in allen vier Fällen *H*-Teilchen (Fehlergrenze 5%) einwandfrei festgestellt; somit auch die Zertrümmerbarkeit dieser vier Atomkerne endgültig bewiesen. Die über Zahl und Reichweite der Atomtrümmer sich ergebenden Daten stimmen mit früher in Wien gefundenen Resultaten im großen und ganzen überein.

Einleitung. Vor etwa 1½ Jahren habe ich in dieser Zeitschrift[1] einen Apparat zur Massenbestimmung schneller und seltener Korpuskularstrahlen beschrieben, wobei hauptsächlich an die *e/m*-Bestimmung der bei der Atomzertrümmerung beobachteten „*H*"-Partikeln gedacht war. In derselben Arbeit konnte ich noch über erfolgreiche Messungen an α-Strahlen aus Polonium sowie an natürlichen *H*-Strahlen (aus Paraffin) berichten, später auch an α-Strahlen anderer Herkunft[2]. Anfang 1926 gelangen die ersten einwandfreien Versuche an Atomtrümmern aus Aluminium, die zusammen mit einer Diskussion der zahlenmäßigen Beziehungen im Massenspektroskop an anderer Stelle veröffentlicht sind[3]. Gelegentlich von noch nicht abgeschlossenen Untersuchungen an Actinium, die gemeinsam mit Frl. E. Rona unternommen wurden, trat infolge Platzens einer sehr dünnwandigen Kapillare eine starke radioaktive Verseuchung des Apparates auf, die trotz gründlichster Reinigung nicht völlig beseitigt werden konnte und diesen auf längere Zeit unbrauchbar machte. Er mußte fast zur Gänze neu gebaut werden, um die Versuche mit Atomtrümmern, bei denen wegen der minimalen Ausbeute auch eine schwache Verseuchung einen Erfolg unmöglich macht, fortsetzen zu können.

Für die weitere Arbeit war zunächst beabsichtigt, womöglich andere Nachweismethoden zu verwenden, von denen die von G. Ortner und dem

§ 1. Problemstellung.

Es ist heute sehr wahrscheinlich geworden, daß Protonen und Neutronen die einzigen elementaren Bausteine der Kerne sind. Da die Ruhenergien dieser Teilchen groß sind gegen die Bindungsenergien der Kerne, sollte man ihre Bewegung im Kern in erster Näherung nach der unrelativistischen Quantenmechanik beschreiben können[1]. Wenn die Kräfte zwischen den Elementarteilchen bekannt wären, müßte es also im Prinzip möglich sein, die Bindungsenergien, d. h. die Massendefekte aller Atomkerne zu berechnen. Da die Versuche, diese Kräfte direkt theoretisch zu bestimmen[2], noch nicht zu eindeutigen Ergebnissen geführt haben, sind wir vorläufig auf den umgekehrten Weg angewiesen: auf die Ableitung der Kernkräfte aus den empirisch bekannten Massendefekten.

Die Massendefekte der leichtesten Kerne sind heute aus den Energiebilanzen von Zertrümmerungsprozessen sehr genau bekannt[3]. Mit etwas geringerer Genauigkeit umfassen die massenspektroskopischen Messungen von Aston und Bainbridge[4] Elemente aus dem ganzen periodischen System. Ergänzt werden diese Angaben durch die oberen Schranken für die Bindungsenergien[5], die sich aus dem Zerfall oder der Nichtexistenz gewisser Kerne gewinnen lassen: z. B. muß das radioaktive Isotop N_7^{13} jedenfalls eine geringere Bindungsenergie haben als C_6^{13}, da es spontan in diesen Kern zerfällt. Das Erfahrungsmaterial zeigt im wesentlichen die folgenden Gesetzmäßigkeiten:

8.4.2 Shell Model

The most puzzling detail of nuclear models was working out the shell model of the "magic numbers" of protons and neutrons that are required to fill different energy levels or shells within the nucleus. Victor Goldschmidt (Swiss, 1888–1947), Walter Elsasser (German, 1904–1991), and Kurt M. Guggenheimer (German, 19??–19??) made very insightful proposals in the 1930s that partially explained the shell model's magic numbers. (Elsasser was a brilliant polymath who, among other insights, also developed the dynamo model that explains how the Earth's magnetic field is generated by the Earth's core—see p. 740 [Rubin 1995].) The final details of the shell model were worked out in the 1940s by Otto Haxel (German, 1909–1998), Johannes Hans Jensen (German, 1907–1973), Maria Goeppert Mayer (German, 1906–1972), Hans Suess (Austrian, 1909–1993), and Eugene Wigner (Hungarian, 1902–1995).

Johannes Hans Jensen, Maria Goeppert Mayer, and Eugene Wigner won the 1963 Nobel Prize in Physics for their contributions to nuclear models. Professor I. Waller of the Nobel Committee for Physics gave an overview of their contributions, as well as those of Walter Elsasser, Otto Haxel, and Hans Suess [https://www.nobelprize.org/prizes/physics/1963/ceremony-speech/]:

> In order to be able to calculate the motion of the nucleons it was, however, necessary to know also the forces which act between them. A very important step in the investigation of these forces was taken by Wigner in 1933 when he found, deducing from some experiments, that the force between two nucleons is very weak except when their distance apart is very small but that the force is then a million times stronger than the electric forces between the electrons in the outer part of the atoms. Wigner discovered later other important properties of the nuclear forces.
>
> Notwithstanding the efforts of many physicists our knowledge of the nuclear forces is yet rather incomplete. It was therefore fundamentally important that Wigner could show that most essential properties of the nuclei follow from generally valid symmetries of the laws of motion. Earlier Wigner had performed pioneering work by studying such symmetries in the laws of motion for the electrons and had made important discoveries by investigating e.g. those symmetries which express the fact that the laws mentioned make no difference between left and right and that backward in time according to them is equivalent to forward in time. These investigations were extended by Wigner to the atomic nuclei at the end of the 1930's and he explored then also the newly discovered symmetry property of the force between two nucleons to be the same whether either of the nucleons is a proton or a neutron. This work by Wigner and his other investigations of the symmetry principles in physics are important far beyond nuclear physics proper. His methods and results have become an indispensable guide for the interpretation of the rich and complicated picture which has emerged from recent years' experimental research on elementary particles. [...]
>
> Wigner has made many other important contributions to nuclear physics. He has given a general theory of nuclear reactions and has made decisive contributions to the practical use of nuclear energy. He has, often in collaboration with younger scientists, broken new paths in many other domains of physics.

It was found during the 1920's and in particular during the 1930's that the protons and the neutrons each form particularly stable systems in an atomic nucleus when the numbers of either kind of nucleons is one of the so-called magic numbers 2, 8, 20, 28, 50, 82 and 126. Several physicists, in particular Elsasser, tried to interpret the magic numbers in analogy to Niels Bohr's successful explanation of the periodic system of the elements. It was then assumed that the nucleons move in orbits in a common field of force and that these orbits are arranged in so-called shells which are energetically well separated. The magic numbers should correspond to complete shells. This interpretation was successful for light nuclei. It was, however, not possible to explain more than the three first magic numbers and for many years another model dominated.

A paper published by Goeppert Mayer in 1948 marked the beginning of a new era in the appreciation of the shell model. For the first time convincing evidence was there given for the existence of the higher magic numbers and it was stressed that the experiments support the existence of closed shells very strongly.

Somewhat later Goeppert Mayer and independently Haxel, Jensen and Suess published the new idea, which was needed for the explanation of the higher magic numbers. The idea was that a nucleon should have different energies when it “spins” in the same or opposite sense as it revolves around the nucleus.

Goeppert Mayer and Jensen collaborated later on the development of the shell model. They published together a book, where they applied the model to the extensive experimental material on atomic nuclei. They gave convincing evidence for the great importance of the shell model in systematizing this material and predicting new phenomena concerning the ground state and the low excited states of the nuclei. The general methods introduced by Wigner have been most important for the applications of the shell model. It has also been possible to give a deeper justification of the shell model. Its fundamental importance has thereby been further confirmed.

8.5 Nuclear Fission Reactions

Fission is the separation of a large (parent) nucleus into two smaller nuclei, and it can be either spontaneous (essentially a form of radioactive decay) or induced by neutron absorption. In addition to the two smaller nuclei, fission also generally produces a few loose neutrons and a large amount of energy. If the loose neutrons from one fission reaction are absorbed by other nuclei and cause them to fission as well, leading to the release of still more fission-inducing neutrons, a chain reaction can occur. Because a chain reaction can cause many nuclei to undergo fission and release their energy within a short period of time, it can be used to create everything from controlled fission power reactors to uncontrolled fission explosives.

In 1934, fission reactions were first theoretically predicted by Ida Tacke Noddack (German, 1896–1978), who together with her husband Walter Noddack (German, 1893–1960) had previously discovered the elements rhenium and technetium (p. 436). See Figs. 8.17–8.18. In the following quote from her often-overlooked but astonishing paper, Ida Noddack correctly predicted both neutron-induced fission of uranium and neutron capture/beta decay in uranium to produce element 93 (later named neptunium), which would beta decay to element 94 (later named plutonium) that could be easily chemically separated from the remaining parent uranium [Noddack 1934]:

Man kann ebensogut annehmen, daß bei dieser neuartigen Kernzertrümmerung durch Neutronen erheblich andere “Kernreaktionen” stattfinden, als man sie bisher bei der Einwirkung von Protonen- und α-Strahlen auf Atomkerne beobachtet hat. Bei den letztgenannten Bestrahlungen findet man nur Kernumwandlungen unter Abgabe von Elektronen, Protonen und Heliumkernen, wodurch sich bei schweren Elementen die Masse der bestrahlten Atomkerne nur wenig ändert, da nahe benachbarte Elemente entstehen. Es wäre denkbar, daß bei der Beschießung schwerer Kerne mit Neutronen diese Kerne in mehrere größere Bruchstücke zerfallen, die zwar Isotope bekannter Elemente, aber nicht Nachbarn der bestrahlten Elemente sind.	One could assume equally well that when neutrons are used to produce nuclear disintegrations, some distinctly new nuclear reactions take place which have not been observed previously with proton or alpha-particle bombardment of atomic nuclei. In the past one has found that transmutations of nuclei only take place with the emission of electrons, protons, or helium nuclei, so that the heavy elements change their mass only a small amount to produce near neighboring elements. When heavy nuclei are bombarded by neutrons, it is conceivable that the nucleus breaks up into several large fragments, which would of course be isotopes of known elements but would not be neighbors of the irradiated element.
[...] aus dem β-strahlenden Element 93 das Element 94 entstehen müßte. Dieses Element sollte man verhältnismäßig leicht chemisch von 93 trennen können.	[...] Beta decay of element 93 must produce element 94. It should be relatively easy to separate this element chemically from element 93.

At the Kaiser Wilhelm Institute for Chemistry in Berlin-Dahlem, Otto Hahn (German, 1879–1968) and Fritz Strassmann (German, 1902–1980) experimentally demonstrated neutron-induced fission of uranium into lighter elements in 1938 (Fig. 8.18), and published their results in January 1939 [Hahn and Strassmann 1939]:

> [...] Bei der energetisch nicht leicht zu verstehenden Bildung von Radiumisotopen aus Uran beim Beschießen mit langsamen Neutronen war eine besonders gründliche Bestimmung des chemischen Charakters der neu entstehenden künstlichen Radioelemente unerläßlich. Durch die Abtrennung einzelner analytischer Gruppen von Elementen aus der Lösung des bestrahlten Urans wurde außer der großen Gruppe der Transurane eine Aktivität stets bei den Erdalkalien (Trägersubstanz Ba), den seltenen Erden (Trägersubstanz La) und bei Elementen der vierten Gruppe des Periodischen Systems (Trägersubstanz Zr) gefunden. Eingehender untersucht wurden zunächst die Bariumfällungen, die offensichtlich die Anfangsglieder der beobachteten isomeren Reihen enthielten. Es soll gezeigt werden, daß Transurane, Uran, Protactinium, Thorium und Actinium sich stets leicht und vollständig von der mit Barium ausfallenden Aktivität trennen lassen. [...]

> [...] Since it is not easy to understand from energy considerations how radium isotopes can be produced when uranium is bombarded with slow neutrons, a very careful determination of the chemical properties of the new artificially made radioelements was necessary. Various analytic groups of elements were separated from a solution containing the irradiated uranium. Besides the large group of transuranic elements, some radioactivity was always found in the alkaline-earth group (barium carrier), the rare-earth group (lanthanum carrier), and also with elements in group IV of the periodic table (zirconium carrier). The barium precipitate was the first to be investigated more thoroughly, since it apparently contains the parent isotopes of the observed isomeric series. The goal was to show that the transuranic elements, and also uranium, protactinium, thorium, and actinium could always be separated easily and completely from the activity which precipitates with barium. [...]

The fission reaction results of Hahn and Strassmann were further analyzed in 1939 by Lise Meitner (Austrian, 1878–1968, Fig. 8.18) and her nephew Otto Frisch (Austrian, 1904–1979, photo on p. 1554). The news of fission reactions provoked strong scientific and political responses around the world, immediately launched major nuclear programs in Germany, the United States, and the United Kingdom, aroused interest that eventually gave rise to serious nuclear programs in many other countries, and of course made possible everything from fission reactors to fission bombs.

For his research on fission, Otto Hahn won the 1944 Nobel Prize in Chemistry, which was delayed by the war as well as his postwar internment at Farm Hall in the United Kingdom (p. 3336). In awarding the Prize, Professor A. Westgren of the Nobel Committee in Chemistry noted [https://www.nobelprize.org/prizes/chemistry/1944/ceremony-speech/]:

> In collaboration with Lise Meitner, with whom he has worked for nearly thirty years, Hahn studied from 1936 to 1938 the products obtained by projecting neutrons on to the heaviest elements, thorium and uranium. [...] But towards the end of 1938, Hahn, in an investigation carried out with one of his young colleagues, F. Strassmann, found that one of the products formed through the reaction of uranium with neutrons and which had been assumed to be a kind of radium, behaved chemically in fact like barium. In

> January 1939 Hahn announced this discovery and expressed in very discreet terms the daring opinion that on being allied with neutrons, the atoms of the heaviest elements could split in half as it were and produce elements belonging to the middle of the Periodic Table of the elements. [...]
>
> Hahn's discovery caused great surprise and evoked lively interest among the world's scientists. It was immediately made the object of important theoretical investigations by Lise Meitner and Frisch, who based their study on the theory of the structure of atomic nuclei developed by Bohr. [...]
>
> Without equal in the art of the chemical identification of radioactive elements in minute quantities, Hahn, together with his colleagues, paved the way for the chemical research which had to be carried out on the numerous products of the splitting of heavy atomic nuclei. [...]
>
> The discovery of nuclear fission is very momentous and indeed dangerous, but even more, it is full of promise. [...]
>
> Hahn's work has been inspired throughout by an invincible desire to solve the problems which he has encountered.

For much more information on the history of nuclear fission research in the German-speaking world, see Appendix D.

Fission Process

$$\frac{E_{\text{Coulomb}}}{E_{\text{surface}}} \propto \frac{Z^2}{A} \sim \begin{array}{l}\text{0.4 Z}\\ \text{for heavy}\\ \text{nuclei}\end{array}$$

Fission barrier height:

$V_B \sim 9\,A^{2/3}\,[1 - (Z^2/A)/49]$ MeV

$$+\begin{cases} 0.3\ \text{MeV} & \text{if odd-odd}\\ 0\ \text{MeV} & \text{if odd-even}\\ -0.3\ \text{MeV} & \text{if even-even}\end{cases}$$

+ shell corrections

~ 5.6 MeV for even U/Pu isotopes

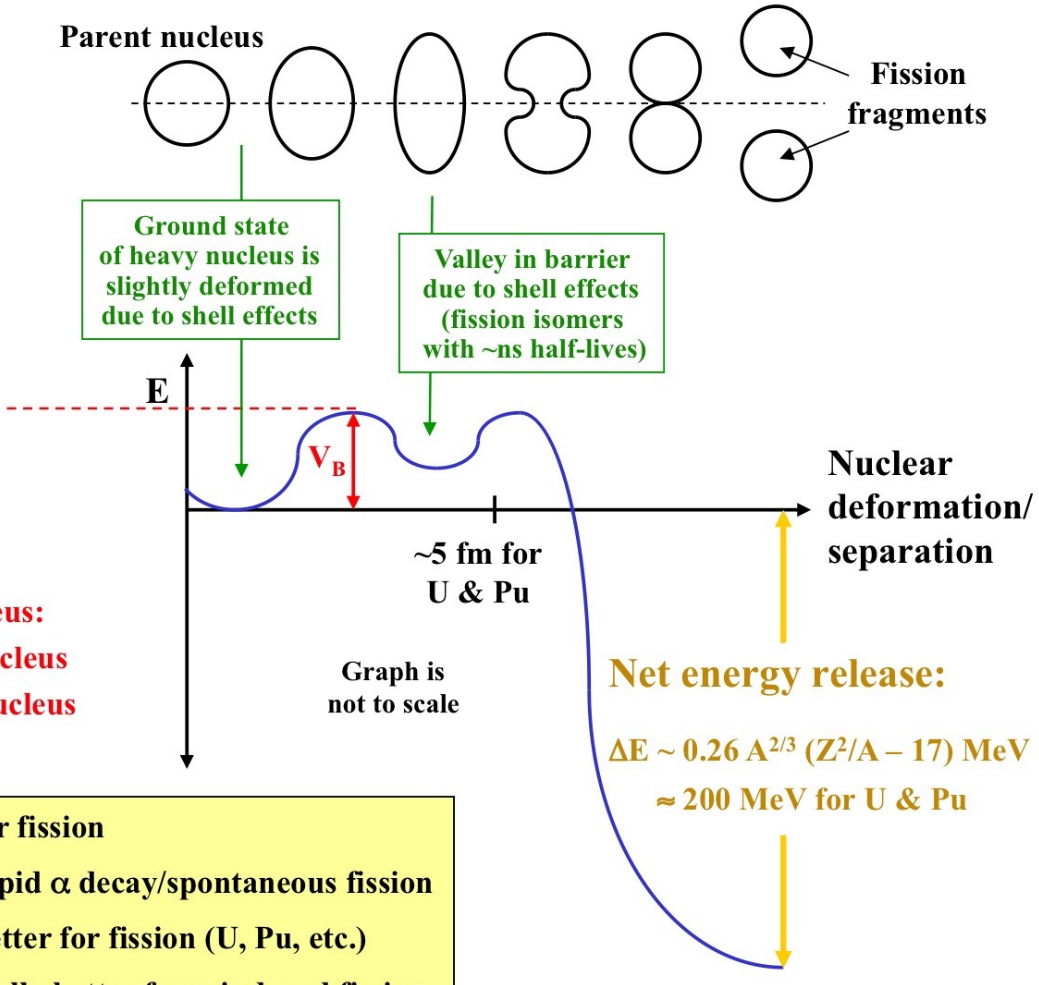
~ 6.2 MeV for odd U/Pu isotopes

Captured neutron adds energy to nucleus:

~ 5 MeV for even U/Pu compound nucleus

~ 6.5 MeV for even-odd compound nucleus

- Z < 90: barrier too high for fission
- Z > 96: barrier too low; rapid α decay/spontaneous fission
- Even-Z nuclei generally better for fission (U, Pu, etc.)
- Odd-N target nuclei generally better for n-induced fission (^{235}U vs. ^{238}U, etc.)



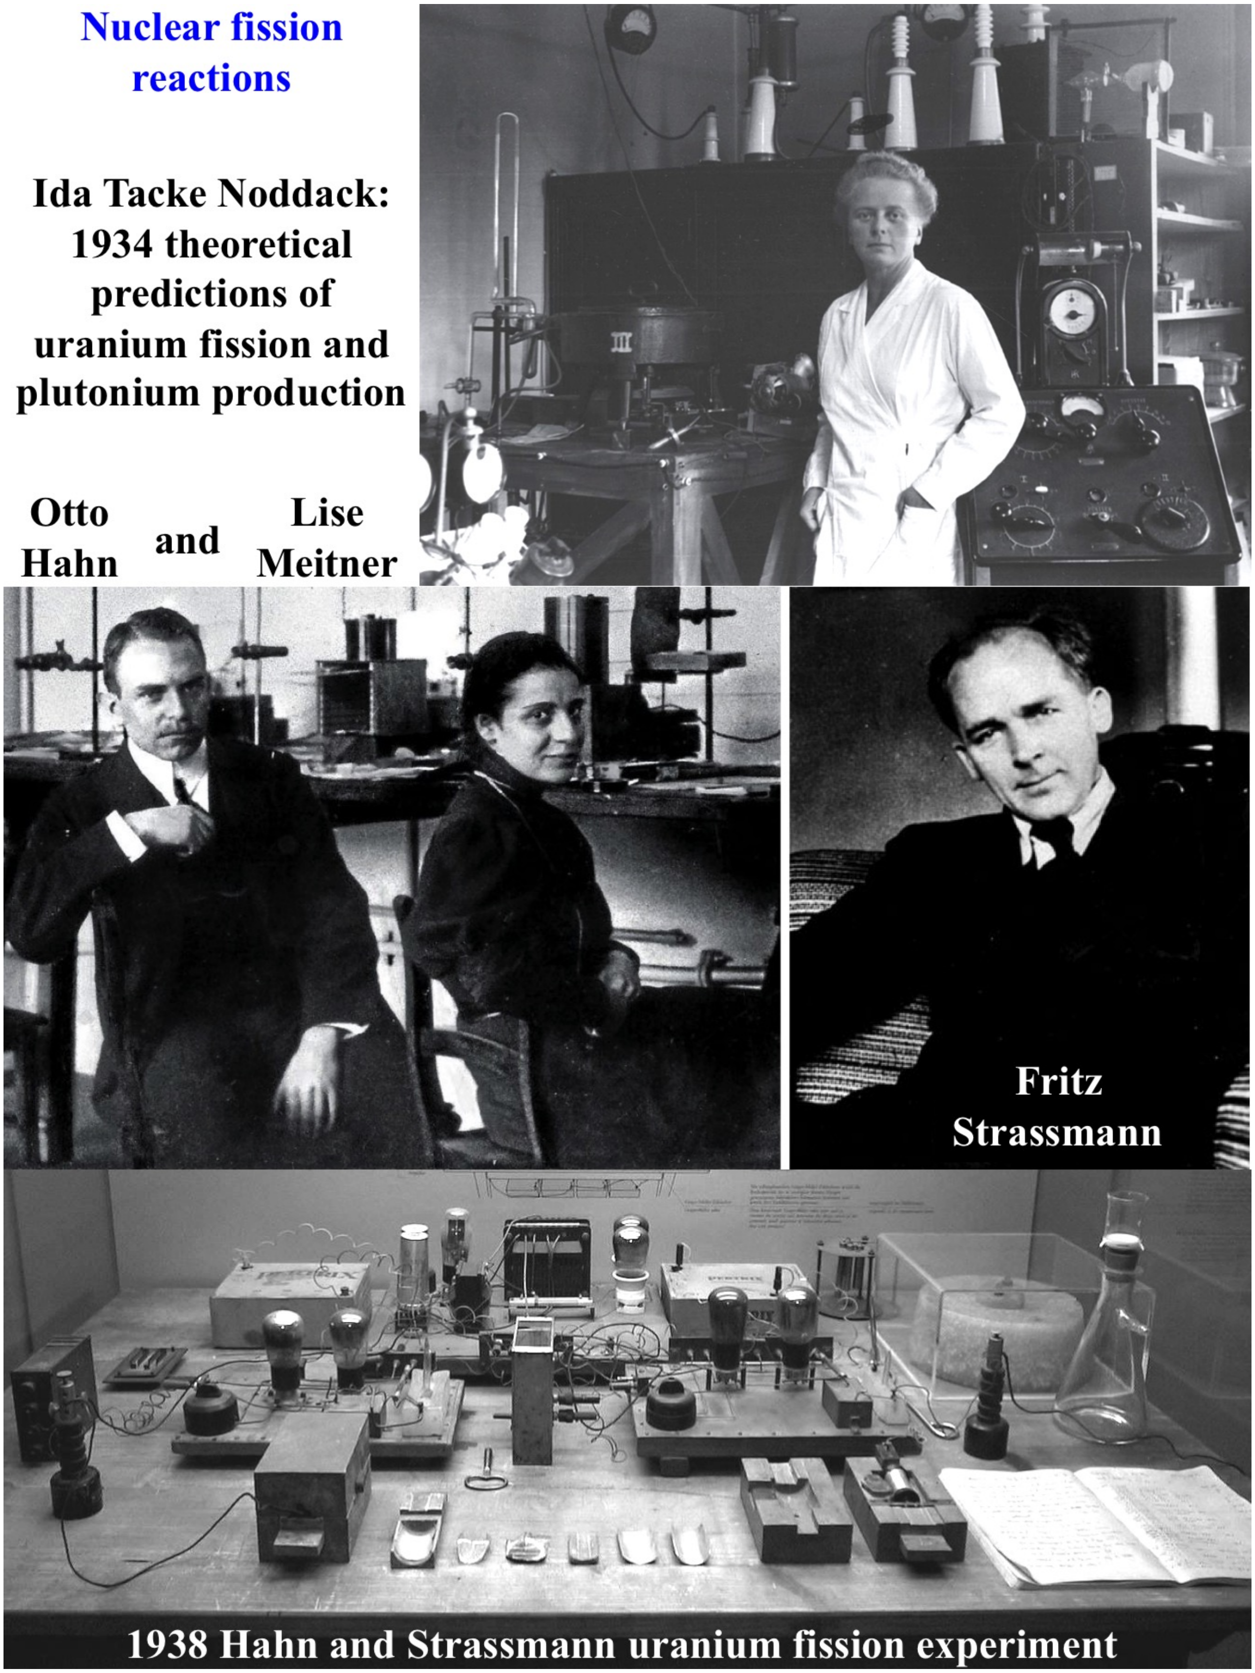
Parent nucleus
Fission fragments
Ground state of heavy nucleus is slightly deformed due to shell effects
Valley in barrier due to shell effects (fission isomers with ~ns half-lives)
E
V_B
Nuclear deformation/ separation
~5 fm for U & Pu
Graph is not to scale

Net energy release:

$\Delta E \sim 0.26\,A^{2/3}\,(Z^2/A - 17)$ MeV

≈ 200 MeV for U & Pu

Figure 8.17: The fission reaction rate depends on the potential energy peak or fission barrier that one nucleus must pass through in order to become two separate nuclei. The parent nucleus undergoing fission has Z protons, N neutrons, and $A = Z + N$ nucleons.



Nuclear fission reactions
Ida Tacke Noddack: 1934 theoretical predictions of uranium fission and plutonium production
Otto Hahn
and
Lise Meitner
Fritz Strassmann
1938 Hahn and Strassmann uranium fission experiment

Figure 8.18: In 1934, Ida Tacke Noddack accurately predicted both the neutron-induced fission of uranium and the production of a new fissile element 94 (later named plutonium) via neutron capture in uranium. Otto Hahn and Fritz Strassmann demonstrated uranium fission reactions in their 1938 experiment, and then Lise Meitner and her nephew Otto Frisch provided further theoretical analysis.

8.6 Nuclear Fusion Reactions

In fusion, two small nuclei join together to form a larger nucleus, generally releasing a large amount of energy in the process. Forcing small nuclei together even though they are positively charged and repel each other typically requires enormous thermal energies (temperatures) and pressures. If fusion fuel is so dense and so well confined that the energy released by one fusion reaction is trapped within the fuel and triggers additional fusion reactions, a chain reaction of fusion reactions can occur (analogous to the chain reaction of fission reactions). Stars and hydrogen bombs are both sufficiently large and dense to trap the fusion energy and sustain a fusion chain reaction. To date it has not been possible to create a practical fusion reactor, though, since too much of the fusion energy escapes from any system that is smaller (and less destructive) than a hydrogen bomb.

Fusion reactions such as those that power the sun and other stars were proposed and theoretically analyzed by Fritz Houtermans (German, 1903–1966) and his student Robert Atkinson (British but studied in Germany, 1898–1982) in 1928, and published in 1929 (Figs. 8.19–8.20). The abstract from that paper demonstrates the remarkable and very early insight that Houtermans and Atkinson had [Atkinson and Houtermans 1929a]:

> Die quantenmechanische Wahrscheinlichkeit dafür, daß ein Proton in einen Atomkern eindringt, wird nach der Methode von Gamow berechnet. Dabei zeigt sich, daß unter den Temperatur- und Dichteverhältnissen im Innern der Sterne die Eindringung von Protonen, nicht aber von α-Teilchen, in leichtere Elemente genügend häufig vorkommt, um dort einen Aufbau dieser Elemente wahrscheinlich erscheinen zu lassen. Daraus ergibt sieh die Möglichkeit, die Energieentwicklung der Sterne auss den Massendefekten der Elemente zu erklären, wobei die Annahme von Sechserstößen für den He-Aufbau vermieden wird. Hieran schließen sich einige weitere hypothetische Betrachtungen über den Aufbau der schwereren Elemente.

> The quantum-mechanical probability of a proton penetrating into an atomic nucleus is calculated by Gamow's method. It is found that for the temperature and density values in the interior of the stars, the penetration of protons, but not of alpha particles, into lighter elements is sufficiently frequent to make a fusion of these elements probable. This gives us the possibility of explaining the energy production of the stars by the mass defects of the elements, avoiding the assumption of six steps for the production of helium. This is followed by a few other hypothetical considerations on the structure of the heavier elements.

The detailed theory of fusion reactions was refined during the period 1937–1939 by Carl Friedrich von Weizsäcker and Hans Bethe (German, 1906–2005). For that work, Bethe won a Nobel Prize in Physics in 1967. In the award ceremony speech for Bethe, Professor O. Klein of the Swedish Academy of Sciences explained [https://www.nobelprize.org/prizes/physics/1967/ceremony-speech/]:

> [...] At that time it was already apparent that Bethe belonged to the small group of young theoretical physicists who through skill and knowledge were particularly qualified for tackling the many theoretical problems turning up in close connection with the rapidly appearing experimental discoveries. The centre of these problems was to find the properties of the force that keeps the protons and neutrons together in the nucleus, the counterpart of the electric force which binds the atomic electrons to the nucleus.

> Bethe's contributions to the solution of these problems have been numerous and are still continuing. They put him clearly in the first row among the workers in this field – as in several other fields. Moreover, about the middle of the thirties he wrote, partly alone, partly together with some colleagues, what nuclear physicists at the time used to call the Bethe bible, a penetrating review of about all that was known of atomic nuclei, experimental as well as theoretical.
>
> This extensive and profound knowledge of his regarding atomic nuclei together with a rare gift of rapidly grasping the essence of a physical problem and finding ways of solving it explains that Bethe could so swiftly do the work awarded by the Nobel Prize. He started his work after a conference taking place in Washington in March 1938 and the paper containing a thorough description of it was delivered for print at the beginning of September the same year. During that conference and afterwards he seems also to have acquired the necessary astrophysical knowledge. [...]
>
> [...] If it were not for the quantum-mechanical tunnel effect studied very closely in this connection by Gamow – who must be considered the main forerunner of Bethe with respect to the application of nuclear physics to astronomy – even the velocities of the protons at the high temperature of the sun would not be able to produce any such processes. But through this effect the required slow reactions do occur. [...]
>
> A very important part of his work resulted in eliminating a great number of thinkable nuclear processes under the conditions at the centre of the sun, after which only two possible processes remained. The simplest of them begins with two protons colliding and forming a nucleus of heavy hydrogen, the surplus of electric charge vanishing in the form of a positive electron. After capturing a few more protons the result of the process is the formation of a helium nucleus from four protons. Thereby the energy release from a given weight of hydrogen is nearly 20 million times greater than that produced by burning the same weight of carbon into carbon dioxide. The second process is more complicated. It requires the presence of carbon which, however, will practically not be consumed but acts as a catalyst, the result being the same as in the former process. It should be mentioned that the first process had been proposed a few years earlier by Atkinson and later discussed by von Weizsacker, who also considered the second process independently of and at about the same time as Bethe. [...]

Hans Bethe

Figure 8.20: Friedrich “Fritz” Houtermans and his student Robert Atkinson described and calculated nuclear fusion reactions in stars in 1928–1929. Carl Friedrich von Weizsäcker and Hans Bethe refined those calculations 1937–1939.

8.7 Nuclear Engineering in the United States and United Kingdom

A large number of scientists who were trained in the German-speaking research world moved temporarily or permanently to the United States and/or United Kingdom and made vital contributions to those countries' nuclear programs both during and after World War II.[5] Some examples of German-speaking and German-educated scientists who played critical roles in the U.S./U.K. nuclear programs are listed in Table 8.1 and shown in Figs. 8.21–8.27. The table and figures also list a few other scientists who were very closely coupled into the German research system during their careers, such as Niels Bohr, a Dane, and Enrico Fermi, an Italian. Note that even the American-born J. Robert Oppenheimer, who was the scientific director of the wartime nuclear program, the Manhattan Project, had a German father and second-generation German-American mother, was raised speaking German, repeatedly visited family in Germany during his childhood, and received his Ph.D. in Germany under Max Born at Göttingen University.

The U.S. nuclear program was initiated by a 2 August 1939 letter to Franklin Roosevelt from two refugees from the German-speaking scientific world, Albert Einstein (who signed the letter) and Leo Szilard (who helped write the letter) [Fig. 8.21 and https://www.atomicarchive.com/resources/documents/beginnings/einstein.html]:

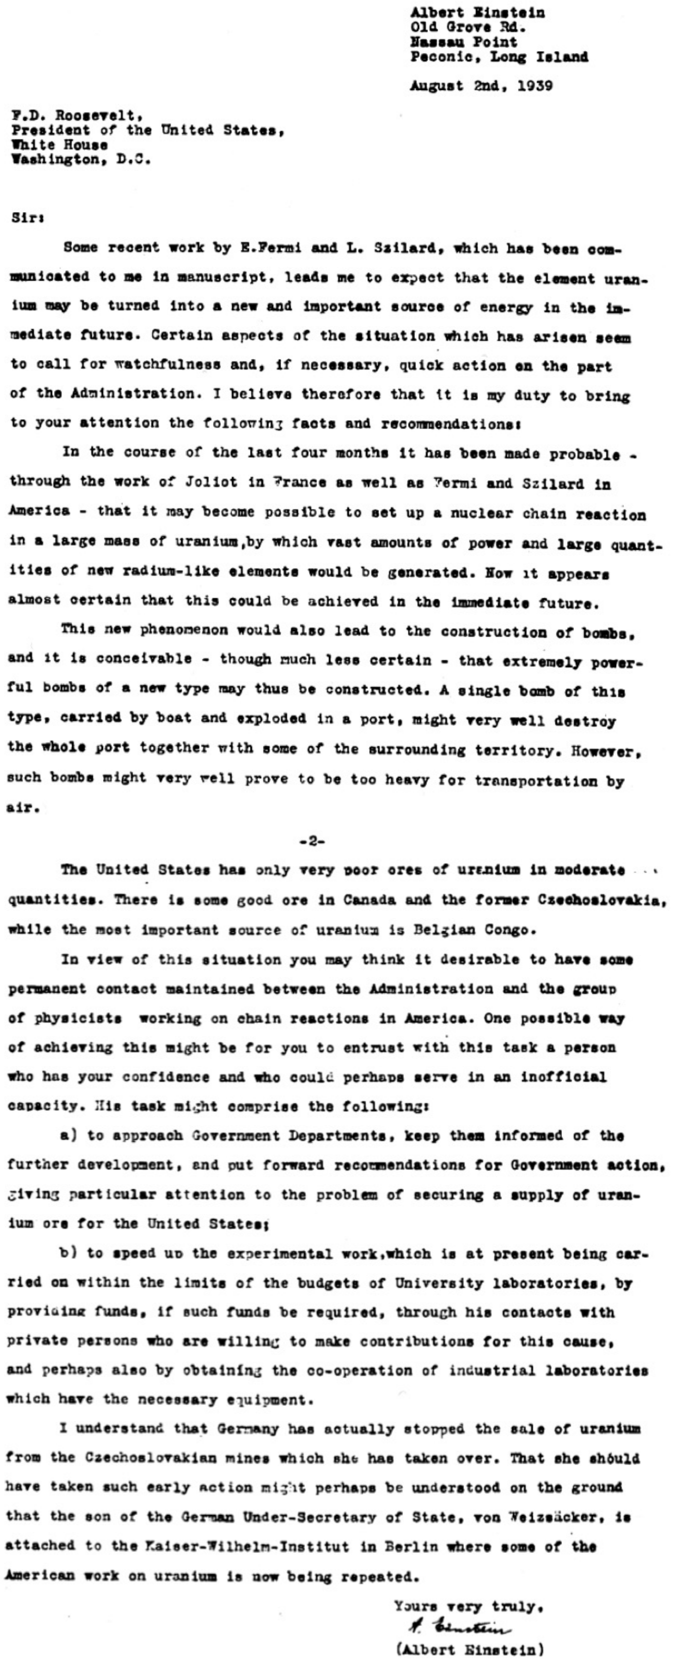
One possible way of achieving this might be for you to entrust with this task a person who has your confidence and who could perhaps serve in an unofficial capacity. His task might comprise the following:
>
> a) to approach Government Departments, keep them informed of the further development, and put forward recommendations for Government action, giving particular attention to the problem of securing a supply of uranium ore for the United States;
>
> b) to speed up the experimental work, which is at present being carried on within the limits of the budgets of University laboratories, by providing funds, if such funds be required, through his contacts with private persons who are willing to make contributions for this cause, and perhaps also by obtaining the co-operation of industrial laboratories which have the necessary equipment.
>
> I understand that Germany has actually stopped the sale of uranium from the Czechoslovakian mines which she has taken over. That she should have taken such early action might perhaps be understood on the ground that the son of the German Under-Secretary of State, von Weizsäcker, is attached to the Kaiser-Wilhelm-Institut in Berlin where some of the American work on uranium is now being repeated.
>
> Yours very truly,
>
> Albert Einstein

Einstein's letter prompted Franklin Roosevelt to authorize the initiation of what would become the Manhattan Project, and of course Einstein's famous equation $E = mc^2$ was the foundation for how a tiny fraction of the mass of fission fuel could be converted into an enormous (and potentially enormously destructive) amount of energy. In March 1940, Einstein and Szilard wrote a second letter to Roosevelt that successfully persuaded him to accelerate the nuclear program. Later, Einstein carried out calculations to help the United States use gaseous diffusion to enrich uranium (concentrate the fissionable U-235 isotope of uranium). Separately, he worked with the U.S. Navy on various military projects. Nonetheless, U.S. government officials such as J. Edgar Hoover distrusted Einstein's longtime inclination toward pacifism and excluded him from the official Manhattan Project [Isaacson 2007, pp. 469–486].



Albert Einstein
Old Grove Rd.
Nassau Point
Peconic, Long Island

August 2nd, 1939

F.D. Roosevelt,
President of the United States,
White House
Washington, D.C.

Sir:

Some recent work by E.Fermi and L. Szilard, which has been communicated to me in manuscript, leads me to expect that the element uranium may be turned into a new and important source of energy in the immediate future. Certain aspects of the situation which has arisen seem to call for watchfulness and, if necessary, quick action on the part of the Administration. I believe therefore that it is my duty to bring to your attention the following facts and recommendations:

In the course of the last four months it has been made probable - through the work of Joliot in France as well as Fermi and Szilard in America - that it may become possible to set up a nuclear chain reaction in a large mass of uranium,by which vast amounts of power and large quantities of new radium-like elements would be generated. Now it appears almost certain that this could be achieved in the immediate future.

This new phenomenon would also lead to the construction of bombs, and it is conceivable - though much less certain - that extremely powerful bombs of a new type may thus be constructed. A single bomb of this type, carried by boat and exploded in a port, might very well destroy the whole port together with some of the surrounding territory. However, such bombs might very well prove to be too heavy for transportation by air.

-2-

The United States has only very poor ores of uranium in moderate quantities. There is some good ore in Canada and the former Czechoslovakia, while the most important source of uranium is Belgian Congo.

In view of this situation you may think it desirable to have some permanent contact maintained between the Administration and the group of physicists working on chain reactions in America. One possible way of achieving this might be for you to entrust with this task a person who has your confidence and who could perhaps serve in an inofficial capacity. His task might comprise the following:

a) to approach Government Departments, keep them informed of the further development, and put forward recommendations for Government action, giving particular attention to the problem of securing a supply of uranium ore for the United States;

b) to speed up the experimental work,which is at present being carried on within the limits of the budgets of University laboratories, by providing funds, if such funds be required, through his contacts with private persons who are willing to make contributions for this cause, and perhaps also by obtaining the co-operation of industrial laboratories which have the necessary equipment.

I understand that Germany has actually stopped the sale of uranium from the Czechoslovakian mines which she has taken over. That she should have taken such early action might perhaps be understood on the ground that the son of the German Under-Secretary of State, von Weizsäcker, is attached to the Kaiser-Wilhelm-Institut in Berlin where some of the American work on uranium is now being repeated.

Yours very truly,
A. Einstein
(Albert Einstein)

Table 8.1 (continued).

Likewise, the U.K. nuclear program was also initiated by two refugees from the German-speaking world, Otto Frisch and Rudolf Peierls. In a March 1940 memorandum to the U.K. government, they wrote [https://www.atomicarchive.com/resources/documents/beginnings/frisch-peierls.html]:

> The attached detailed report concerns the possibility of constructing a "super-bomb" which utilises the energy stored in atomic nuclei as a source of energy. The energy liberated in the explosion of such a super-bomb is about the same as that produced by the explosion of 1,000 tons of dynamite. This energy is liberated in a small volume, in which it will, for an instant, produce a temperature comparable to that in the interior of the sun. The blast from such an explosion would destroy life in a wide area. The size of this area is difficult to estimate, but it will probably cover the center of a big city.
>
> In addition, some part of the energy set free by the bomb goes to produce radioactive substances, and these will emit very powerful and dangerous radiations. The effects of these radiations is greatest immediately after the explosion, but it decays only gradually and even for days after the explosion any person entering the affected area will be killed.
>
> Some of this radioactivity will be carried along with the wind and will spread the contamination; several miles downwind this may kill people.
>
> In order to produce such a bomb it is necessary to treat a substantial amount of uranium by a process which will separate from the uranium its light isotope (U235) of which it contains about 0.7 percent. Methods for the separation of such isotopes have recently been developed. They are slow and they have not until now been applied to uranium, whose chemical properties give rise to technical difficulties. But these difficulties are by no means insuperable. We have not sufficient experience with large-scale chemical plant to give a reliable estimate of the cost, but it is certainly not prohibitive.
>
> It is a property of these super-bombs that there exists a "critical size" of about one pound. A quantity of the separated uranium isotope that exceeds the critical amount is explosive; yet a quantity less than the critical amount is absolutely safe. The bomb would therefore be manufactured in two (or more) parts, each being less than the critical size, and in transport all danger of a premature explosion would be avoided if these parts were kept at a distance of a few inches from each other. The bomb would be provided with a mechanism that brings the two parts together when the bomb is intended to go off. [...]

The U.S. and U.K. nuclear programs eventually joined together for the duration of the war under the umbrella of the Manhattan Project. As listed in Table 8.1 and shown in Figs. 8.28–8.30, German-speaking and German-trained scientists played critical roles in all areas of the Manhattan Project, including enriching uranium, developing fission reactors, producing plutonium, and creating fission bombs. The fission reactor technologies that they developed were ultimately used to power everything from nuclear submarines to commercial electric generation plants.

There is also evidence that some scientists who had spent the war in Germany may have materially contributed to the U.S. nuclear program in the crucial final months of the war (see p. 4692 for more details). For example, when the German submarine U-234 surrendered to the United States in May 1945, it was found to contain 560 kg of uranium oxide (possibly enriched), infrared fuses that may have been suitable for implosion bombs, at least two experts on those materials (Gerhard Falck for the uranium and Heinz Schlicke for the infrared fuses), and potentially other nuclear-related materials and information. As another important example, Hans Kammler, who was in charge of virtually all advanced German weapons programs (including the nuclear program) by the end of the war, was secretly captured and kept indefinitely by the United States for extended interrogations (see pp. 4931–4959). In view of the fact that the United States never turned him over to the Nuremberg war crimes trials or even informed those trials that Kammler was alive and in U.S. custody, it seems likely that Kammler provided the United States with valuable information and/or materials. It is possible that assistance from these and other German sources may have appreciably accelerated the delivery schedule for the first U.S. fission bombs and also helped the postwar U.S. nuclear program. Much more archival research is needed to address this question.

After the war, many of these German-speaking and German-educated scientists (most notably Edward Teller and Stanislaw Ulam) went on to create the first U.S. fusion bombs (hydrogen or H-bombs) in 1952 and 1954. Postwar U.S./U.K. nuclear programs were also aided directly or indirectly by an influx of many additional German and Austrian scientists who were from or at least had knowledge of the German nuclear program, such as Karl-Friedrich Bonhoeffer, Wernher von Braun, Rudolf Brill, Adolf Busemann, Walter Dornberger, Rudolf Edse, Krafft Ehricke, Wilhelm Eitel, Gerhard Falck, Karl Fiebinger, Wolfgang Finkelnburg, Rudolf Fleischmann, Siegfried Flügge, Walter Glaser, Wilhelm Groth, Gottfried Guderley, Paul Harteck, Otto Haxel, Richard Herzog, Johannes Hans Jensen, Willibald Jentschke, Ulrich Jetter, Georg Joos, Hartmut Kallmann, Hans Kammler, Gerald Klein, Stanley Kronenberg, Heinz Maier-Leibnitz, Werner Maurer, Hugo Neuert, Walter Nielsch (?), Edgar Petersen, Heinz Schlicke, Otto Schwede, Erich Schumann, Edmund Sorg, Kurt Starke, Ernst Stuhlinger, Hans Suess, Herbert Wagner, Wilhelm Westphal, Friedwardt Winterberg, Karl Wirtz, Gernot Zippe, etc. (p. 4992).

For more information on the influence of the wartime German nuclear program on the wartime and postwar U.S./U.K. nuclear programs, see Sections 8.8.14 and D.14.

Klaus Fuchs, who had spent many years working on the U.S./U.K. fission and fusion bomb programs, was discovered in 1950 to have been forwarding details of those programs to the Soviet Union throughout that time; he was imprisoned in the United Kingdom before being handed over to East Germany in 1959. Some scientists such as Rudolf Fleischmann, Siegfried Flügge, and Johannes Hans Jensen returned to Europe sooner or later. However, most of the German-trained scientists continued their careers in nuclear and defense fields in the United States, in some cases exerting their influence for many decades (Edward Teller died in 2003 and Hans Bethe died in 2005).

Of course, the massive U.S. nuclear weapons program was built up by U.S. industries, and employed many notable U.S.-born scientists, such as Ernest Lawrence, Glenn Seaborg, and John Wheeler and his freshly graduated student Richard Feynman. Nonetheless, for a program that involved over 100,000 people and was critical to the U.S. war effort, it is remarkable how many of the key innovations were made by scientists who came from the German-speaking world. One must wonder how rapidly the U.S. nuclear program would have advanced if it had not had the benefit of any personnel or information from the greater German-speaking scientific world.

Even the Atomic Heritage Foundation, based in Washington D.C. and founded to celebrate the history and success of the United States nuclear program, has publicly recognized the role that scientists from the greater German-speaking world played in that program [www.atomicheritage.org/article/scientist-refugees-and-manhattan-project]:

> One of the ironies of Hitler's desire for racial purity was that it drove out of continental Europe or into the camps many individuals who would have been extremely useful to the Axis war effort. Nowhere was this more evident than in the effort to produce an atomic bomb. A startling proportion of the most famous names on the project belonged to scientists who came to England or America to flee from the Axis. The large number of refugees and immigrants working on the Manhattan Project gave the American nuclear program an international character unusual in such a top-secret program—and unique amongst the nuclear programs that followed in other countries—and helped give life in Los Alamos, NM during the war its unique character.

Figure 8.30: Examples of early U.S. fission reactors: plutonium-producing reactors were constructed at Hanford, Washington during the period 1943–1963; the USS *Nautilus* (SSN-571), the first submarine powered by a fission reactor, was launched in 1954.

8.8 Nuclear Engineering in the Third Reich

This section presents evidence which suggests that the World War II German nuclear program was much larger and much more advanced than has previously been generally understood. While this claim may seem controversial, much of the relevant archival evidence has only been declassified and rediscovered in recent years, and was not publicly available when earlier historical assessments were made. The evidence presented here covers:

8.8.1. Flaws in the conventional historical view of the German program.

8.8.2. The fundamental scientific knowledge and planning of the program.

8.8.3. Sources of uranium and thorium.

8.8.4. Enrichment of uranium-235.

8.8.5. Fission reactors for breeding plutonium-239 and/or uranium-233.

8.8.6. Electronuclear systems for breeding plutonium-239 and/or uranium-233.

8.8.7. The production of other potentially nuclear-related materials.

8.8.8. Fission bomb designs.

8.8.9. Hydrogen bomb designs.

8.8.10. An October 1944 test explosion on the Baltic coast.

8.8.11. A circa November 1944 test explosion in Poland.

8.8.12. March 1945 test explosions in Thuringia.

8.8.13. Axis belief in the reality of German nuclear weapons.

8.8.14. Allied belief in the reality of German nuclear weapons.

8.8.15. Further research that is needed.

For a far more detailed presentation of the currently available evidence, see Appendix D. As explained in Section 8.8.15, much more work is needed to uncover and evaluate evidence regarding the true history and extent of the wartime nuclear program.

8.8.1 Flaws in the Conventional Historical View of the German Program

The conventional historical view that has been held from 1945 to the present is that the World War II German nuclear program was very small and poorly funded, that Germany was still trying to complete its first prototype fission reactor when the war ended, and that Germany never even made a serious attempt to develop nuclear weapons.[6] This view is based on three categories of evidence, although each category has its own limitations as summarized below and in Section D.1:

---

[6] E.g., Goudsmit 1945, Goudsmit 1947; Groves 1962; Hentschel and Hentschel 1996; Hoffmann 2023; Irving 1967; Pash 1969; Popp 2016, 2021; Powers 1993; Rhodes 1986; Rose 1998; Walker 1989, 1995, 2020, 2024a, 2024b.

1. The U.S.-led Alsos Mission searching for evidence of nuclear-related work at the end of the war found the incomplete fission reactor at Haigerloch, some papers on basic nuclear physics, and apparently not much else, according to the public accounts. Unfortunately, the Alsos Mission failed to properly investigate numerous specific organizations, scientists, and locations that could have revealed a more advanced nuclear program. If any more advanced nuclear work had in fact been discovered, that information would have been automatically classified at the time, and could remain classified or buried in archives and unreleased to this day.[7]

2. Ten German nuclear scientists (Erich Bagge, Kurt Diebner, Walther Gerlach, Otto Hahn, Paul Harteck, Werner Heisenberg, Horst Korsching, Max von Laue, Carl Friedrich von Weizsäcker, and Karl Wirtz) rounded up by the Alsos Mission were kept under house arrest from July 1945 until January 1946 at Farm Hall in the United Kingdom, where their private conversations were recorded without their knowledge. The transcripts, which were not released to the public until 1992, record the scientists' surprise at news of the 6 August 1945 Hiroshima bombing and do not reveal significant apparent knowledge of nuclear weapons design and development. However, a huge number of relevant nuclear scientists were not at Farm Hall. There is evidence that those who were there suspected surveillance and conducted their conversations accordingly. The preserved transcripts document only a small fraction of the discussions that would have occurred among ten people and their British attendants during those six months. Moreover, the transcripts are English translations, which may not accurately reflect the original German conversations. Both the original recordings and the original German transcripts are said to have been permanently lost, a shocking lapse for such an important operation.[8]

3. In their public interviews and writings in the years after the war, German nuclear scientists professed a lack of desire, plans, materials and/or political support to produce nuclear weapons for the Third Reich. On the other hand, only a small number of nuclear scientists went on the public record. It is not clear how much of what they said was factual history versus personal spin meant to avoid postwar criticism; the answer may vary for different scientists in question. Certainly it would have been in their best personal interests to downplay their support for weapons-related work as much as possible.[9]

With access to some of the previously unavailable former Soviet and East German archives and witness testimony, as well as newly discovered and released U.S. and British documents, beginning in the 1990s several authors argued (with varying degrees of success and accuracy) that wartime German work on nuclear weapons was actually much more extensive, involved many more scientists, and progressed much further than had been accepted by the conventional historical narrative.[10]

8.8.2 Fundamental Knowledge and Planning

There is ample documentation that the German nuclear program began very early and with great determination (Section D.2).[11]

In 1934, Ida Tacke Noddack accurately predicted both the neutron-induced fission of uranium and the production of a new fissile element 94 (later named plutonium-239, ^{239}Pu) via neutron capture in uranium (p. 1537).

Also in 1934, the experimental nuclear physicist Kurt Diebner (German, 1905–1964) began working closely with the implosion expert Erich Schumann (German, 1898–1985) at the Heereswaffenamt (Army Ordnance Office), which seems to indicate just how early the military applications and necessary methods of nuclear technologies were envisioned (p. 3376). Both Diebner and Schumann appear to have played hugely important roles in the development of nuclear weapons through the end of the war.

Germany seized control of the St. Joachimsthal (or Jáchymov) uranium mine in Czech territory in 1938 and made the mining and shipment of uranium from there to sites in Germany and Austria a high priority throughout the entire war [Hayes 2004, pp. 132–133, 235, 243]. See also p. 3998.

German organizations began operating and receiving shipments from a uranium mine at Buchovo (or Buhovo), a suburb of Sofia, Bulgaria, in 1938 [Hayes 2004, p. 235; https://ejatlas.org/conflict/life-after-the-uranium-mines-in-buhovo-bulgaria]. See also p. 4588.

Germany also acquired control of a number of other sources of uranium and thorium (Section 8.8.3).

At the Kaiser Wilhelm Institute (KWI) for Chemistry, Otto Hahn and Fritz Strassmann experimentally confirmed Noddack's prediction of the neutron-induced fission of uranium into lighter elements in 1938. They published their results in January 1939 (p. 1538).

In April 1939, Paul Harteck (Austrian, 1902–1985) and Wilhelm Groth (German, 1904–1977) at the University of Hamburg informed the German War Office that nuclear fission could be harnessed to create a strategically decisive bomb many orders of magnitude more powerful than conventional explosives (p. 3364). Harteck and Groth worked on many different important aspects of the German nuclear program throughout the war.

No later than April 1939, the German government was conducting very secret, high-level meetings of nuclear scientists and government officials concerning a program for the strategic military applications of nuclear physics (p. 3376).

---

[11] For comparison with the German timeline, it is instructive to consider the wartime U.S. nuclear program. Despite Albert Einstein's letter to Franklin Roosevelt in August 1939 (p. 1548), the U.S. program languished in committee meetings until it was jolted into action in the aftermath of Pearl Harbor. Leslie Groves was not appointed to head the newly dubbed Manhattan Project until September 1942, and construction of the buildings for the Los Alamos, Oak Ridge, and Hanford facilities did not even begin until early 1943. Serious design work on the Gadget/Fat Man implosion bomb did not begin until August 1944 [Groves 1962; Bruce Cameron Reed 2019; Rhodes 1986].

In June 1939, Siegfried Flügge (German, 1912–1997), a nuclear physicist at the KWI for Chemistry, published calculations showing the feasibility of using pure uranium-235 fuel and fast neutrons to create an explosive chain reaction, estimating both the time scale and energy release for the explosion. He stated: "The energy release happens in such a short time that we are dealing with an extraordinarily violent explosion." In the same article, he explicitly proposed water-moderated fission power reactors using thermal neutrons, derived and used the neutron diffusion and kinetics equations that are still taught in modern nuclear engineering textbooks, and correctly stated that cadmium could be used as a neutron absorber to maintain control of the neutron-induced fission reactions (p. 3366). Due to this and his other papers, Flügge apparently became the chief theorist of the German nuclear weapons program. He ended up working simultaneously for many different organizations that were all involved in the nuclear program—including the KWI, Reichspost (Postal Service), Heereswaffenamt, Reichsforschungsrat (Reich Research Council), SS, and universities—apparently serving to coordinate the scientific details of all of their activities (p. 4998).

Georg Stetter (Austrian, 1895–1988) led a large and advanced nuclear physics group at the University of Vienna. In June 1939, he filed a patent application that included a remarkably detailed description of a fission reactor (p. 3372). Stetter and all of his fellow Austrians seem to have played large roles in the German nuclear weapons program throughout the war.

Around 1939, the experimental physicist and inventor Manfred von Ardenne (German, 1907–1997) joined up with Wilhelm Ohnesorge, the very science-minded and deep-pocketed head of the Reichspost (government postal service, but like an even more advanced version of the U.S. Bell Laboratories), to conduct nuclear-weapons-related work (p. 3376). Due to Ohnesorge's strong support, the Reichspost was one of the most important organizations in the nuclear weapons program throughout the war.

Germany began ordering heavy water from Vemork, Norway in December 1939 (p. 4031). Heavy water would make an excellent moderator to facilitate the operation of a uranium reactor to produce power and/or plutonium.

No later than 1940, Carl Friedrich von Weizsäcker (German, 1912–2007) understood that ^{239}Pu could be used to create a bomb. No later than 1941, von Weizsäcker, Fritz Houtermans (German, 1903–1966), Josef Schintlmeister (Austrian, 1908–1971), and Friedrich Hernegger provided many more details about the properties, production, and military applications of plutonium. See pp. 3794–3826.

During the war, Houtermans and other scientists in the German program also understood how uranium-233 (^{233}U) could be bred from natural thorium-232 (^{232}Th) and used to create a bomb (pp. 3832–3836).

As shown in Fig. 8.31, the wartime nuclear program was spread among the Heereswaffenamt, Kriegsmarine (Navy), Luftwaffe (Air Force), Reichspost, SS, several Kaiser Wilhelm Institutes (KWI), Physikalische-Techische Reichsanstalt (Physical-Technical Reich Institute), several universities, a number of companies, and groups in Czechoslovakia, Poland, Denmark, Norway, and elsewhere.[12] In the early years of the war, the work of these many groups was coordinated by the Heereswaffenamt. From 1942 until the end of the war, the coordination was managed by the SS.

---

[12] See pp. 3376–3403; Irving 1967; Karlsch 2005, Karlsch and Petermann 2007; Nagel 2003, 2011, 2012a, 2016.

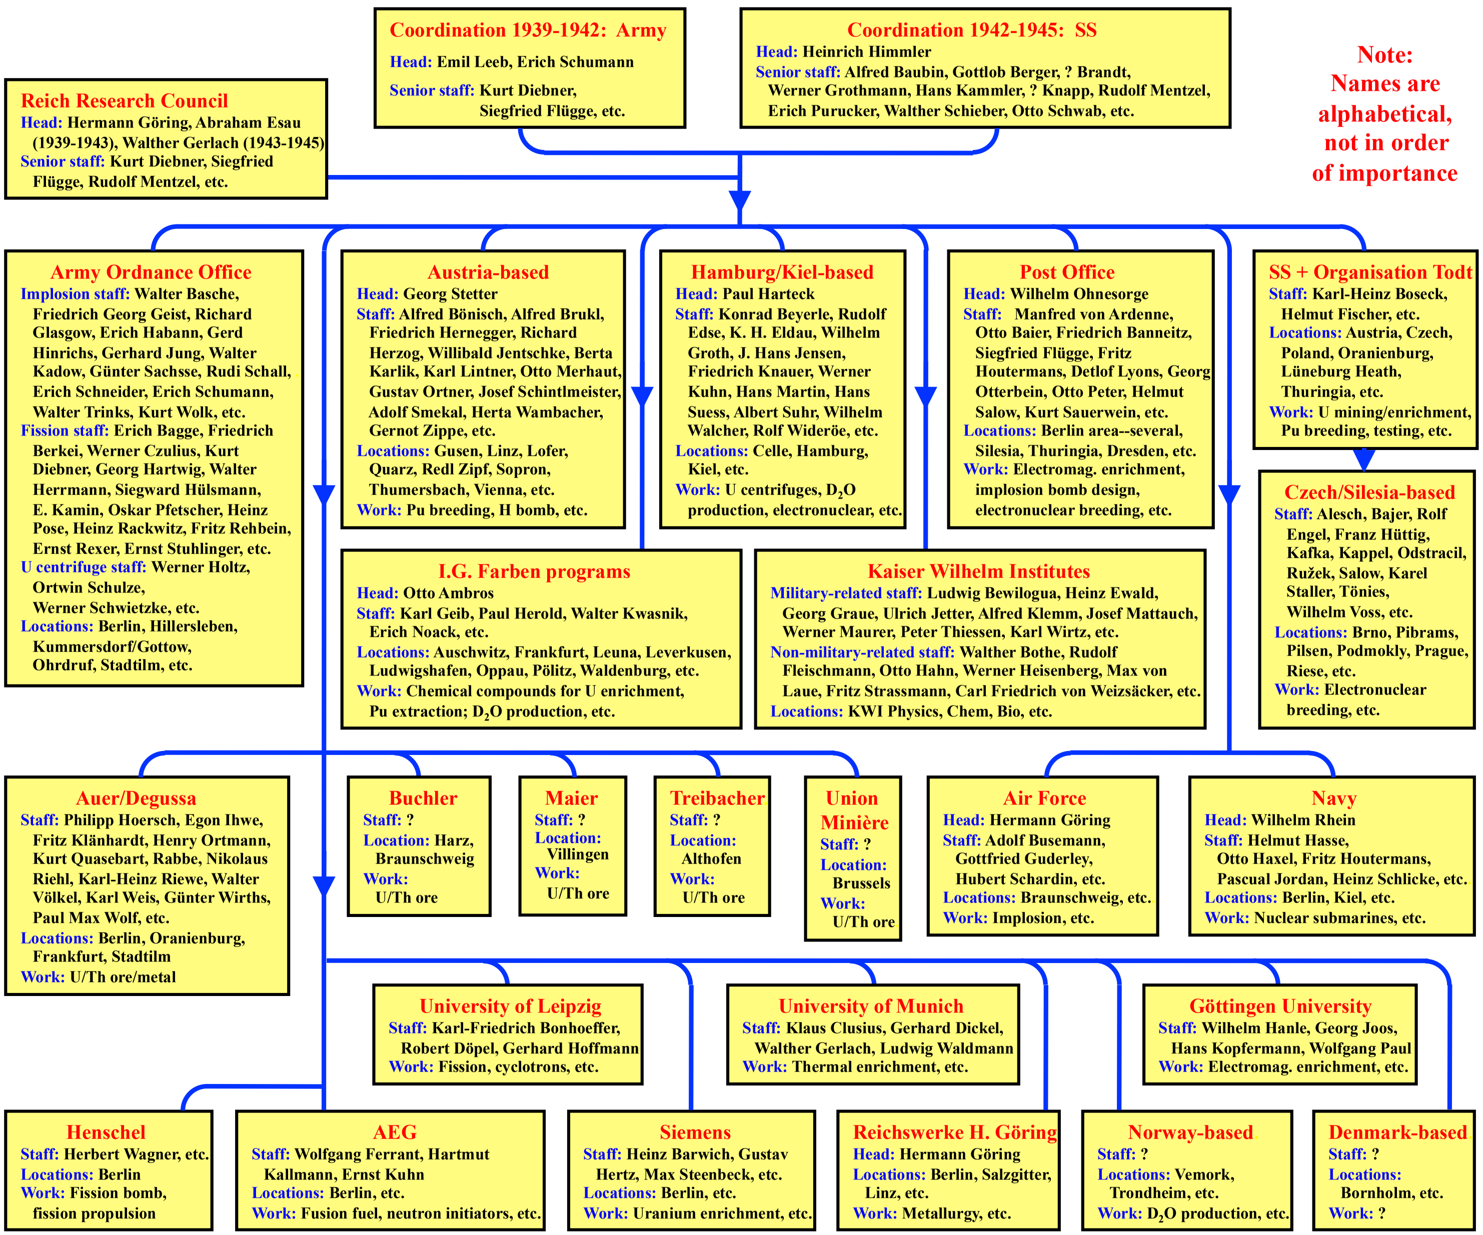
For an incomplete list of some of the more important scientists and engineers in the program, see pp. 1568, 1611–1629.[13] Many of those German-speaking nuclear experts subsequently worked in the postwar Soviet nuclear weapons program (Figs. 8.52–8.55), whereas others visited or moved to the United States or United Kingdom and apparently aided their programs (Figs. 8.22–8.27). Still others went to France or other countries after the war.

Note that for the last 75+ years, conventional histories of the German nuclear program have generally only covered a very small and relatively minor part of what was actually a far larger program.

Because the German nuclear program was so widely dispersed, it was much more resistant to Allied bombing and Allied intelligence; unfortunately that has also made it far more difficult for modern historians to reconstruct the details of the wartime nuclear program and its scientific accomplishments. Adding to the complications for both wartime intelligence and modern historians, the German nuclear program was highly compartmentalized, with individual people and groups only knowing as much as they needed to do their parts, just as the German chemical weapons program and the other most secretive programs were.

---

[13] This list has been compiled from sources throughout the Bibliography and Appendix D, but most of the names can be found in: Hentschel and Hentschel 1996; Hoffmann 2023; Irving 1967; Karlsch 2005, Karlsch and Petermann 2007; Nagel 2003, 2011, 2012a, 2016 Powers 1993 Rose 1998; Walker 1989, 1995, 2020, 2024a, 2024b.



Note: Names are alphabetical, not in order of importance

Reich Research Council
Head: Hermann Göring, Abraham Esau (1939-1943), Walther Gerlach (1943-1945)
Senior staff: Kurt Diebner, Siegfried Flügge, Rudolf Mentzel, etc.

Coordination 1939-1942: Army
Head: Emil Leeb, Erich Schumann
Senior staff: Kurt Diebner, Siegfried Flügge, etc.

Coordination 1942-1945: SS
Head: Heinrich Himmler
Senior staff: Alfred Baubin, Gottlob Berger, ? Brandt, Werner Grothmann, Hans Kammler, ? Knapp, Rudolf Mentzel, Erich Purucker, Walther Schieber, Otto Schwab, etc.

Army Ordnance Office
Implosion staff: Walter Basche, Friedrich Georg Geist, Richard Glasgow, Erich Habann, Gerd Hinrichs, Gerhard Jung, Walter Kadow, Günter Sachsse, Rudi Schall, Erich Schneider, Erich Schumann, Walter Trinks, Kurt Wolk, etc.
Fission staff: Erich Bagge, Friedrich Berkei, Werner Czulius, Kurt Diebner, Georg Hartwig, Walter Herrmann, Siegward Hülsmann, E. Kamin, Oskar Pfetscher, Heinz Pose, Heinz Rackwitz, Fritz Rehbein, Ernst Rexer, Ernst Stuhlinger, etc.
U centrifuge staff: Werner Holtz, Ortwin Schulze, Werner Schwietzke, etc.
Locations: Berlin, Hillersleben, Kummersdorf/Gottow, Ohrdruf, Stadtilm, etc.

Austria-based
Head: Georg Stetter
Staff: Alfred Bönisch, Alfred Brukl, Friedrich Hernegger, Richard Herzog, Willibald Jentschke, Berta Karlik, Karl Lintner, Otto Merhaut, Gustav Ortner, Josef Schintlmeister, Adolf Smekal, Herta Wambacher, Gernot Zippe, etc.
Locations: Gusen, Linz, Lofer, Quarz, Redl Zipf, Sopron, Thumersbach, Vienna, etc.
Work: Pu breeding, H bomb, etc.

Hamburg/Kiel-based
Head: Paul Harteck
Staff: Konrad Beyerle, Rudolf Edse, K. H. Eldau, Wilhelm Groth, J. Hans Jensen, Friedrich Knauer, Werner Kuhn, Hans Martin, Hans Suess, Albert Suhr, Wilhelm Walcher, Rolf Wideröe, etc.
Locations: Celle, Hamburg, Kiel, etc.
Work: U centrifuges, D_2O production, electronuclear, etc.

Post Office
Head: Wilhelm Ohnesorge
Staff: Manfred von Ardenne, Otto Baier, Friedrich Banneitz, Siegfried Flügge, Fritz Houtermans, Detlof Lyons, Georg Otterbein, Otto Peter, Helmut Salow, Kurt Sauerwein, etc.
Locations: Berlin area--several, Silesia, Thuringia, Dresden, etc.
Work: Electromag. enrichment, implosion bomb design, electronuclear breeding, etc.

SS + Organisation Todt
Staff: Karl-Heinz Boseck, Helmut Fischer, etc.
Locations: Austria, Czech, Poland, Oranienburg, Lüneburg Heath, Thuringia, etc.
Work: U mining/enrichment, Pu breeding, testing, etc.

I.G. Farben programs
Head: Otto Ambros
Staff: Karl Geib, Paul Herold, Walter Kwasnik, Erich Noack, etc.
Locations: Auschwitz, Frankfurt, Leuna, Leverkusen, Ludwigshafen, Oppau, Pölitz, Waldenburg, etc.
Work: Chemical compounds for U enrichment, Pu extraction; D_2O production, etc.

Kaiser Wilhelm Institutes
Military-related staff: Ludwig Bewilogua, Heinz Ewald, Georg Graue, Ulrich Jetter, Alfred Klemm, Josef Mattauch, Werner Maurer, Peter Thiessen, Karl Wirtz, etc.
Non-military-related staff: Walther Bothe, Rudolf Fleischmann, Otto Hahn, Werner Heisenberg, Max von Laue, Fritz Strassmann, Carl Friedrich von Weizsäcker, etc.
Locations: KWI Physics, Chem, Bio, etc.

Czech/Silesia-based
Staff: Alesch, Bajer, Rolf Engel, Franz Hüttig, Kafka, Kappel, Odstracil, Ružek, Salow, Karel Staller, Tönies, Wilhelm Voss, etc.
Locations: Brno, Pibrams, Pilsen, Podmokly, Prague, Riese, etc.
Work: Electronuclear breeding, etc.

Auer/Degussa
Staff: Philipp Hoersch, Egon Ihwe, Fritz Klänhardt, Henry Ortmann, Kurt Quasebart, Rabbe, Nikolaus Riehl, Karl-Heinz Riewe, Walter Völkel, Karl Weis, Günter Wirths, Paul Max Wolf, etc.
Locations: Berlin, Oranienburg, Frankfurt, Stadtilm
Work: U/Th ore/metal

Buchler
Staff: ?
Location: Harz, Braunschweig
Work: U/Th ore

Maier
Staff: ?
Location: Villingen
Work: U/Th ore

Treibacher
Staff: ?
Location: Althofen
Work: U/Th ore

Union Minière
Staff: ?
Location: Brussels
Work: U/Th ore

Air Force
Head: Hermann Göring
Staff: Adolf Busemann, Gottfried Guderley, Hubert Schardin, etc.
Locations: Braunschweig, etc.
Work: Implosion, etc.

Navy
Head: Wilhelm Rhein
Staff: Helmut Hasse, Otto Haxel, Fritz Houtermans, Pascual Jordan, Heinz Schlicke, etc.
Locations: Berlin, Kiel, etc.
Work: Nuclear submarines, etc.

University of Leipzig
Staff: Karl-Friedrich Bonhoeffer, Robert Döpel, Gerhard Hoffmann
Work: Fission, cyclotrons, etc.

University of Munich
Staff: Klaus Clusius, Gerhard Dickel, Walther Gerlach, Ludwig Waldmann
Work: Thermal enrichment, etc.

Göttingen University
Staff: Wilhelm Hanle, Georg Joos, Hans Kopfermann, Wolfgang Paul
Work: Electromag. enrichment, etc.

Henschel
Staff: Herbert Wagner, etc.
Locations: Berlin
Work: Fission bomb, fission propulsion

AEG
Staff: Wolfgang Ferrant, Hartmut Kallmann, Ernst Kuhn
Locations: Berlin, etc.
Work: Fusion fuel, neutron initiators, etc.

Siemens
Staff: Heinz Barwich, Gustav Hertz, Max Steenbeck, etc.
Locations: Berlin, etc.
Work: Uranium enrichment, etc.

Reichswerke H. Göring
Head: Hermann Göring
Locations: Berlin, Salzgitter, Linz, etc.
Work: Metallurgy, etc.

Norway-based
Staff: ?
Locations: Vemork, Trondheim, etc.
Work: D_2O production, etc.

Denmark-based
Staff: ?
Locations: Bornholm, etc.
Work: ?

Figure 8.31: Very tentative organizational chart of the German nuclear program.

8.8.3 Sources of Uranium and Thorium

Scientists such as Nikolaus Riehl (German, 1901–1990), Günter Wirths (German, 1911–2005), Egon Ihwe (German, 18??–19??), and many others played vital roles in the processing of uranium and thorium for the German nuclear weapons program (Section D.3). Many of those scientists went on the play equally important roles in the postwar Soviet nuclear weapons program (Section 8.9).

During the war, Germany had access to large amounts of natural uranium and thorium ore by (see map on p. 3405):

- Acquiring at least 1200 tons, and according to some well-informed sources 3500 tons, of uranium compounds (originally mined in the Belgian Congo) from Union Minière in Brussels [e.g., pp. 3335, 3408–3414].
- Expanding uranium mining at St. Joachimsthal (Jachymov), Bohemia [e.g., pp. 3418–3429, 3445, 3469–3470, 4978–4984; Hayes 2004, pp. 132–133, 235, 243].
- Mining uranium at Příbram/Przibram/Pibrans, Bohemia [e.g, pp. 3424, 3470, 3751–3754].

- Mining or planning to mine uranium at Mladkov/Wichstadt, Bohemia [e.g., p. 3425].
- Operating and receiving shipments from Bulgarian uranium mines such as a mine at Buchovo (or Buhovo, a suburb of Sofia), since 1938 [e.g., Hayes 2004, p. 235; https://ejatlas.org/conflict/life-after-the-uranium-mines-in-buhovo-bulgaria]. See also pp. 3446, 3470, 4588.
- Mining uranium at Băiţa-Plai and other sites in Romania [e.g., pp. 3449–3455, 3471].
- Acquiring uranium from mines at Viseu and Guarda, Portugal [e.g., p. 3445; Hayes 2004, p. 235].
- Procuring all available monazite thorium ore in occupied Europe [e.g., Irving 1967].
- Exploiting other possible sources—Spain, Scandinavia, etc.?

One 1946 U.S. intelligence report on Czech uranium mines noted, “The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria” (p. 3998). Another 1946 U.S. intelligence report added: “The Germans continued operations in this mine to the very last moment” (p. 4981).

Thus Germany began actively mining uranium in 1938 and continued until the end of the war. During that time, Germany had access to (1) the same quality and a comparable quantity of Congolese uranium that served the Manhattan Project well, (2) Central/Eastern European uranium mines that later served the Soviet nuclear program well, and (3) additional uranium mines too.

Germany processed uranium and thorium ore to uranium oxide and thorium oxide, and thence to uranium or thorium metal or to a variety of useful chemical compounds—uranium hexafluoride, uranium tetrachloride, uranium nitrate, etc.—at numerous locations including (see map on p. 3407):

- Union Minière in Brussels [e.g., pp. 3335, 3408–3414; Irving 1967, p. 65].
- Auer in Oranienburg, Katowice/Kattowitz, and other locations [e.g., pp. 3446, 3458, 3461–3463, 3465, 4980; Nagel 2016].
- Buchler in Braunschweig [e.g., pp. 3420, 3430–3431, 3458, 3460–3463, 3465, 4980].
- Treibacher Chemische Werke in Althofen, Austria [e.g., pp. 3420, 3432–3437, 3458, 3460, 4980; Gollmann 1994].
- Degussa in Frankfurt, Berlin, Stadtilm, and possibly other locations [e.g., pp. 3458, 3461–3465; Hayes 2004; Nagel 2016].
- Chemische Fabrik Grünau in Berlin [e.g., pp. 3438–3439, 3461–3463].
- I.G. Farben in Leverkusen and other locations [e.g., pp. 3488–3489, 3492–3493, 3678–3680, 3748–3750, 4440–4477; Mader 1965, pp. 193–202, 229-233].
- Krupp in Essen [e.g., pp. 3458, 3461–3463, 3465–3467].
- W. de Boer in Hamburg and Wittingen [e.g., pp. 3458, 3461–3463, 3465].
- Radium-Chemie AG in Frankfurt [e.g., pp. 3440–3441, 3458, 3465].
- W. Maier KG Radiumchemische Industrie und Laboratorium in Villingen-Schwenningen am Neckar and other locations [e.g., Oleynikov 2000].
- Příbram/Przibram/Pibrans, Bohemia [e.g., pp. 3423, 3751–3754].
- Facilities in Dresden [e.g., pp. 3423, 3426].
- Reichswerke Hermann Göring in Linz and other locations [e.g., pp. 3877–3880].
- Possibly other facilities.

At the end of the war, Allied countries removed over 2800 tons of uranium and thorium compounds from former German-controlled territory (p. 3456). In addition, in 1974, Alwin Urff, deputy technical plant manager of the Asse nuclear disposal site in Germany, stated: “When we began storage in 1967, our company first sank radioactive waste from the last war, that uranium waste which arose in the preparation of the German atomic bomb” (p. 3472).

8.8.4 Enrichment of ^{235}U

Only 0.72% of natural uranium is ^{235}U, the fissile isotope. In order to achieve high concentrations of ^{235}U for a fission bomb, it is necessary to enrich or separate ^{235}U from the other uranium isotopes (Section D.4).

Uranium is converted into the gaseous compound uranium hexafluoride (UF_6) for most enrichment processes (except uranium tetrachloride for electromagnetic separation). UF_6 is highly corrosive to most materials except nickel. German reports captured by the Alsos Mission demonstrate that at least as early as 1940, the German program was fully aware of this information and capable of producing UF_6, and that much of that production capability was at I.G. Farben. Some especially noteworthy researchers in the development and handling of UF_6 were Erich Noack (German, 19??–19??) and Walter Kwasnik (German, 19??–19??) at I.G. Farben Leverkusen, and Paul Harteck and Wilhelm Groth in Hamburg (Section D.4.1).

Georg Bredig (German, 1868–1944) demonstrated the first gas centrifuges in 1895, and the technology was further developed by Fritz Haber (German, 1868–1934) and other researchers. By the time of the Third Reich, gas centrifuges for uranium isotope enrichment were built, tested, and even mass-produced by engineers all over the greater German-speaking world (Section D.4.2). Some of the key personnel included Konrad Beyerle (German, 1900–1979), Klaus Clusius (German, 1903–1963), K. H. Eldau (German, 19??–19??), Wilhelm Groth, Paul Harteck, Helmuth Hausen (German, 1895–1987), Werner Holtz (German, 19??–19??), Johannes Hans Jensen (German, 1907–1973, later won a Nobel Prize for the nuclear shell model), Werner Kuhn (Swiss, 1899–1963), Detlof Lyons (German, 19??–19??, also worked for the Reichspost), Hans Martin (German, 19??–19??), R. Schlatterer (German?, 18??–19??), Ortwin Schulze (German, 19??–19??), Werner Schwietzke (German, 1910–1987), Hans Suess (Austrian, 1909–1993), and Albert Suhr (German, 1920–1996).

Currently available documents indicate that gas centrifuges were produced by:

- Anschütz in Kiel (pp. 3494–3515).
- PHYWE (Physicalische Werkstatte) in Göttingen (pp. 3542–3544), which also made extremely advanced liquid centrifuges for biochemical research (pp. 2397–2399).
- Linde Eismaschinen in Munich (pp. 3498–3507), which had decades of experience with gas handling and rotating compressor machinery.
- Hellige in Freiburg (pp. 3512–3540).
- Hellige in Breslau/Wrocław (p. 4522).
- One or more factories in Switzerland for export to Germany (pp. 3545–3548).
- Quite possibly other locations as well.

How many uranium gas centrifuges were produced by or for Germany during the war? At what sites were they installed and operated? How much enriched uranium did they produce in total, and how highly enriched was it? Can files that would answer these questions be located in various national archives and declassified?

Centrifugation proved so superior to the U.S. Manhattan Project's enrichment methods that the German gas centrifuge designs are now the worldwide standard for uranium enrichment (pp. 3549–3553). The evidence clearly shows that the technology was developed and demonstrated over the course of half a century (1895–1945) by German scientists and engineers, and spread by German scientists and engineers (as well as the prototypes and documentation they had produced) to other countries after the war. The Soviet Union was one of those countries to which the technology spread (via scientists such as Max Steenbeck and Gernot Zippe), but not the origin of the technology [Benedict et al. 1981; Glaser 2008; Helmbold 2016; Kemp 2009, 2012, 2017; NYT 2004-03-23].

Manfred von Ardenne (German, 1907–1997), Heinz Ewald (German, 1914–1992), Wolfgang Paul (German, 1913–1993), Wilhelm Walcher (German, 1910–2005), and many others worked in teams to develop electromagnetic separators (called calutrons in the United States) to enrich uranium (Section D.4.3). By 1941, von Ardenne and his collaborators had built and successfully demonstrated a prototype electromagnetic separator, and were trying to persuade German industry to mass-produce such separators. In March 1942 Ewald delivered a final report on calculations for the optimal performance of electromagnetic separators. According to a June 1944 OSS report, von Ardenne, Siegfried Flügge, and the Reichspost (which was working closely with the SS) had supervised the construction of three secretive high-voltage facilities at undisclosed locations. Were those three electromagnetic enrichment facilities? Von Ardenne became a central figure in the Soviet nuclear weapons program after the war.

Gustav Hertz (German, 1887–1975) patented gaseous diffusion separation in 1923 and a gaseous diffusion cascade system in 1925. Hertz, Erika Cremer (German, 1900–1996), Hubert Krüger (German, 18??–19??), Rudolf Fleischmann (German, 1903–2002), Erich Bagge (German, 1912–1996), and others built and demonstrated prototype gaseous diffusion enrichment systems before and during the war (Section D.4.4). Hertz's secret wartime work was deemed so important by the German government that he was allowed to live and work in relative comfort throughout the war despite his Jewish ancestry. After the war, he played a vital role in the Soviet nuclear program.

After the war, leftover wartime factories in Neustadt an der Orla, East Germany, were already perfectly set up to make high-quality nickel membrane filters for gaseous diffusion enrichment plants (pp. 3633–3638, 5052, 5055–5057). Manufacturing the filters was so difficult that even years after the war, Soviet plants could not make comparable items. What exactly did these German factories do during the war?

Stanisław Mrozowski (Polish, 1902–1999), K. Zuber (Swiss, 19??–19??), Werner Kuhn, Hans Martin, K. H. Eldau, Paul Harteck, and others developed photochemical methods of isotope separation, demonstrated them with elements such as mercury, and worked to apply them to uranium (Section D.4.5). Although it is currently unclear how far that work progressed during the war, it became the basis of laser isotope separation after the war. (For early work toward lasers in the German-speaking world, see Section C.3).

As a basis for comparison, one can consider the U.S. uranium enrichment facility at Oak Ridge, Tennessee. For the 12 months ending 1 September 1945, the total electrical consumption for Oak Ridge (Y-12 calutrons + K-25 gaseous diffusion + all other nuclear facilities + the town itself) was 1659 GW hr for the year, or 0.189 GW time-averaged (pp. 5122–5123).

At the end of 1944 the Greater German Reich (Grossdeutsches Reich) had a total known electrical production capacity of at least 22–23 GW, despite territorial losses, extensive bombing, and ongoing repairs (pp. 2102–2106). Including secretive or specialized power plants for classified or dedicated projects within the Greater German Reich that were not known to the Allied investigators plus the electrical production capacities of other countries that were occupied by Germany, allied with Germany, or nominally neutral but exporting aid to Germany, a reasonable estimate of the total electrical production capacity supporting the German war effort is roughly double the 22–23 GW figure, or ∼44–46 GW.

Using the average total electrical consumption of Oak Ridge during the final year of the war, Germany could have powered a fully equal facility by using less than 1% of the known wartime electrical capacity in the Greater German Reich, or less than 0.5% of the estimated total electrical production capacity that was available to aid Germany during the war. German centrifuges would have been more energy-efficient than U.S. enrichment methods, and the German implosion design would have needed much less ^{235}U than the U.S. Little Boy, so German uranium enrichment plants may have required far less total electrical power than Oak Ridge.

If Germany scaled up any of its proven uranium enrichment methods during the war, rather than building one giant Oak-Ridge-like plant that could be highly vulnerable to Allied bombing, it would have distributed its enrichment capability among a number of (especially underground) locations. Indeed, that is exactly what was done, according to a declassified October 1944 OSS report based on information from Adolf Schneider, a senior manager of the Deutsche Waffen und Munitions-Fabrik (pp. 4400–4403).

Archival documents, most of which are found in the declassified files of the OSS and the Manhattan Project's Foreign Intelligence Unit, mention dozens of highly suspicious sites that might have been used for that purpose and that have never been properly investigated, at least not publicly (Section D.4.6). Just a few illustrative examples are given below.

An October 1943 OSS intelligence report from Frederick Loofbourow described what sound like underground uranium enrichment facilities staffed by hundreds of workers near Lüneburger Heide. There were also other reports of nuclear-related work at Lüneburger Heide (pp. 4176–4182, 4406).

A May 1944 OSS intelligence report described what sound like two massive uranium enrichment facilities, each with 30,000 workers, run by I.G. Farben in Opava and Ostrava in eastern Czech territory (p. 3748).

Julius Schaub, Hitler's chief adjutant, stated there was another 30,000-worker uranium enrichment facility at an underground site in Thuringia (4635–4639).

Several sources mentioned Reichspost enrichment facilities on the outskirts of Berlin (pp. 3608–3617, 3708–3709, 4635–4639).

Throughout the war, large amounts of electricity were consumed by high-security weapons work that produced no obvious products (Sections D.4.6 and 8.8.11).

In September 1946, General Leslie Groves (the head of the U.S. nuclear weapons program) sent Percival C. Keith (the construction chief of the Oak Ridge enrichment plant) on a two-week Top Secret mission to Czechoslovakia (pp. 3770–3771). What target would involve Groves, require the specific expertise of Keith, and justify the great risk if Keith were captured by Czech or Soviet forces? Was Keith's mission to help inspect, remove, or destroy key components of a wartime enrichment facility?

As a quantitative example of what might have been required of a German enrichment facility, one can consider the case of electromagnetic separation, using the U.S. calutrons at the Oak Ridge Y-12 plant for reference. In early 1945, Y-12 was producing approximately 0.2 kg ^{235}U per day, or approximately 73 kg/year. The U.S. electromagnetic separation plant was designed to produce so much ^{235}U because the United States planned to use that uranium in Little Boy, a gun-type fission bomb that needed over 60 kg of fuel since it did not compress the fuel and had a very low efficiency. The U.S. plant provided enough uranium for approximately one bomb of that design per year.

The sources that describe the German fission bomb design all indicate that it was an implosion bomb (Section 8.8.8), which compresses the fuel, is much more efficient than a gun-type bomb, and therefore requires roughly 1/10 as much fuel as a gun-type bomb. If a German enrichment facility were designed to produce enough ^{235}U for one full-sized bomb per year (or several test bombs with smaller amounts of fuel and smaller explosive yields, as described by the sources), a German electromagnetic enrichment plant could have been roughly 1/10 the size of the U.S. Y-12 plant, as extrapolated in Table 8.2. Likewise, Table 8.3 shows the extrapolated characteristics of a hypothetical German centrifuge separation plant. If that same production capacity were distributed among several production plants to minimize the risk of Allied bombing (p. 4400), each plant would have been even smaller.

Characteristic	**U.S. Y-12 Plant**	**Hypothetical German Plant**
^{235}U production rate	73 kg/year	$\sim$ 7 kg/year
Number of ion beams	3120	$\sim$ 310
Number of workers	22,482	$\sim$ 2,200
Facility floor space	$\sim$ 400,000 m^2	$\sim$ 40,000 m^2
Electric power consumption	200 MW	$\sim$ 20 MW
Cost (1940s U.S. dollars)	$477,631,000	$\sim$ $48,000,000

Table 8.2: Known characteristics of the U.S. electromagnetic separation plant and extrapolated characteristics of a hypothetical German electromagnetic separation plant. (See Section D.15.2.A for details.)

Characteristic	**Hypothetical German Plant**
^{235}U production rate	$\sim$ 7 kg/year
Number of centrifuges	$\sim$ 467
Number of workers	$<$ 1,400
Facility floor space	$<$ 4,200 m^2
Electric power consumption	$<$ 1 MW
Cost (1940s U.S. dollars)	$<$ $48,000,000

Table 8.3: Extrapolated characteristics of a hypothetical German centrifuge separation plant. (See Section D.15.2.C for details.)

8.8.5 Fission Reactors for Breeding ^{239}Pu and/or ^{233}U

The available documentation shows that German scientists were aware that either ^{239}Pu or ^{233}U would make good fuel for fission bombs (Section D.5) and could be produced in a fission reactor by the following respective processes:

$$^{238}_{92}\mathrm{U} + \mathrm{n} \xrightarrow{(\mathrm{n},\gamma)} {}^{239}_{92}\mathrm{U} \quad \beta \xrightarrow{23.5\ \mathrm{min}} {}^{239}_{93}\mathrm{Np} \quad \beta \xrightarrow{2.36\ \mathrm{days}} {}^{239}_{94}\mathrm{Pu} \tag{8.1}$$

$$^{232}_{90}\mathrm{Th} + \mathrm{n} \xrightarrow{(\mathrm{n},\gamma)} {}^{233}_{90}\mathrm{Th} \quad \beta \xrightarrow{21.8\ \mathrm{min}} {}^{233}_{91}\mathrm{Pa} \quad \beta \xrightarrow{27.0\ \mathrm{days}} {}^{233}_{92}\mathrm{U} \tag{8.2}$$

^{237}Np fission fuel [Sanchez et al. 2008] could also have been bred in fission reactors (e.g., by knocking a neutron out of ^{238}U), although it probably would have been more difficult to produce in quantity than ^{239}Pu or ^{233}U [Benedict et al. 1981].

Ludwig Bewilogua (German, 1906–1983), Kurt Diebner, Paul Harteck, Otto Haxel (German, 1909–1998), and many others worked in teams trying to develop suitable fission reactors.

By far the best known German reactor was the one built by Werner Heisenberg's group, first located at the KWI for Physics in Berlin-Dahlem, and later moved to Haigerloch (pp. 3843–3853). It never achieved criticality (a self-sustaining neutron chain reaction) during the war. There were also smaller subcritical fission experiments, such as those built by Robert Döpel's team in Leipzig and Paul Harteck's team in Hamburg.[14]

Throughout the war, Kurt Diebner's Heereswaffenamt group built a series of reactor experiments of increasing size and complexity at Gottow (Kummersdorf) through 1944, and at Stadtilm in 1945 (pp. 3854–3868). According to official histories, Diebner's reactor experiments never achieved criticality during the war. In fact, there is some evidence that they may have achieved criticality in late 1944 and/or early 1945 [Karlsch 2005; Nagel 2016]. However, even if Diebner's reactor did go critical, it was a small experimental system, not a large production reactor for breeding useful quantities of ^{239}Pu or ^{233}U.

There is some evidence that a number of other, larger fission reactors were under construction during the war, and that some of them may have even been operational. Just a few examples are cited here; for more information, see pp. 3840–3953.

There may have been fission reactors and a fuel reprocessing facility near Königsberg (now Kaliningrad) in East Prussia (pp. 3928–3933). Heinrich Himmler's close diplomatic contact, Muhammad Amin Al-Husayni, the Grand Mufti of Jerusalem, reported those reactors after the war (pp. 4578–4579): "After 1945 the Grand Mufti said that the enemy espionage by 'Jewish, English and American intelligence services' caused 'the greatest damage.' They were able to discover the locations of 'atomic reactors' in East Prussia."

As already noted, Siegfried Flügge, who was probably the top nuclear physicist in the German nuclear weapons program, worked for many different organizations that were involved in the program, apparently serving to coordinate the scientific details of all of their activities. Among his many other urgent and nuclear-focused duties, he was appointed to a professorship at the University of Königsberg in 1944, late in the war as Russian forces were advancing (p. 4998). That appointment only makes sense if there was a nuclear facility there that was deemed critical to the war, such as fission reactors breeding plutonium for nuclear weapons.

---

[14] Goudsmit 1947; Groves 1962; Irving 1967; Pash 1969; Powers 1993; Walker 1989.

During the war, Königsberg had a large staff of inorganic chemists with world-class expertise in methods that would have been useful for reprocessing irradiated fuel from fission reactors. After the war, many of those chemists were interrogated by at least two teams from the U.S. Alsos Mission, which suggests that U.S. officials suspected the Königsberg chemists had been involved in nuclear work (pp. 3930–3933).

There were tens of thousands of forced laborers working in and near Königsberg during the war. They are known to have worked with toxic chemicals such as ship paints and suffered the consequences [Jasiński 1994]. This labor pool might also have been used for hazardous nuclear work.

During the period 26–30 August 1944, U.K. Royal Air Force bombers, operating at the very limits of their range, devastated targets in and near Königsberg (p. 3928). That only makes sense if there were targets of great military value and urgency, such as a nuclear facility on the verge of producing enough fuel for nuclear weapons. It also explains the Grand Mufti's comment.

Despite the Allied bombings and fierce offensives by Soviet forces, German troops successfully defended East Prussia until April 1945, rather than retreating to more central areas of Germany and using their strength to defend those. Once again, that only makes sense if there were something in East Prussia that Germany considered to be of great strategic significance until the very end of the war.

After the war, East Prussia was claimed as Soviet territory, even though it was geographically disconnected from any other Soviet territory, rather than allotting it to the surrounding countries, Poland or Lithuania. Again, that suggests something rather unusual was found there. (Of course, it did also provide a desirable seaport for the Soviet Union.)

There are a number of archival documents, witness statements, aerial photographs, and other evidence strongly suggesting that part of the Bergkristall tunnel complex at St. Georgen an der Gusen (near Linz, Austria) was conducting nuclear-weapons-related work during the war (pp. 3874–3920). From some of the evidence, it sounds as if the complex may have included a fission reactor and fuel reprocessing facility. German forces sealed the entrances and air shafts to that part of the tunnel complex shortly before the end of the war, and they have remained sealed for 75+ years. U.S. officials inspected this site and interrogated witnesses after the war (pp. 4962–4970). Their reports on what they found and learned there have never been publicly released. Air and water samples taken from the site in recent years have remarkably high levels of radioactivity, which may or may not be due to purely natural causes. Until all of the documentary evidence is available, and/or until the site can be properly excavated and analyzed, the true nature of this facility cannot be settled.

According to U.S. intelligence reports, there was a highly secret, heavy concrete installation at the I.G. Farben Leverkusen plant that may have been a fission reactor (pp. 3934–3935). It is known that I.G. Farben Leverkusen was doing extensive work involving uranium hexafluoride throughout the war (Section 8.8.4), and that other I.G. Farben facilities were producing many other potentially nuclear-related materials (Section 8.8.7).

According to some sources, a fission reactor was built and operated by the SS, likely in an underground facility in Thuringia, and was reported to have been operational in March 1945 (pp. 3865–3868).

A possible fission reactor at Unterraderach near Friedrichshafen (on the coast of the Obersee Bodensee) was reported to have been operational in 1944 (pp. 3921–3925).

A fission reactor at an underground facility in Berlin-Lichterfelde was reported to have been operational in 1944 (pp. 3926–3928).

According to other sources, there may have been a fission reactor at Bodenbach/Krizik-Werke/Weser-Werke/Podmokly (pp. 3936–3937, 3987–3998).

There is evidence that there may have been additional fission reactors at other locations (pp. 3938–3953).

Heavy water (D_2O) is an excellent moderator for fission reactors. Germany appears to have been producing heavy water in at least 25 plants all over Europe (including several run by I.G. Farben, Section 8.8.7), despite the difficulties of Allied bombing and the urgent wartime needs to produce other materials and products. This additional evidence strongly suggests that Germany possessed operational fission reactors, or at least was trying to get reactors operational as soon as possible.

The Soviet Union demonstrated its first fission reactor (F-1) on 25 December 1946, only about 12 months after its captured German nuclear scientists were able to begin setting up the captured German nuclear materials (including at least 300 tons of German-produced uranium oxide, which fueled both F-1 and the larger second Soviet reactor for breeding Pu-239); see Section 8.9. If German scientists and German materials accomplished that feat so quickly after starting over in the Soviet Union after the war, they certainly could have done it in German territory during the war.

If uranium or thorium is left in a fission reactor too long, much of the ^{239}Pu and/or ^{233}U that had initially been created by neutron bombardment will be fissioned and destroyed by later neutrons. Moreover, prolonged neutron exposure can also breed undesirable isotopes—especially ^{240}Pu from natural uranium or ^{232}U from natural thorium—that are highly radioactive and therefore greatly complicate the handling of that fuel in reprocessing and in bombs. For both of those reasons, large amounts of uranium or thorium fuel are generally moved in and out of breeder reactors over fairly short periods of time.

In the wartime U.S. nuclear program, the main reactors breeding plutonium were three reactors in Hanford, Washington, dubbed reactors B, D, and F. When fully operational, each of those reactors produced approximately 250 MW of thermal power from approximately 250 tons of natural uranium, or about 1 MW/ton. At that power, each reactor bred approximately 0.19 kg of ^{239}Pu per day, or approximately 69 kg per year. To limit the production of ^{240}Pu, the 250 tons of reactor fuel was removed after approximately 100 days, and then the reactor was restarted with fresh natural uranium fuel [Bruce Cameron Reed 2015a, 2019]. Comparing the ^{239}Pu production rate of 0.19 kg/day to the rate of using natural uranium, 250 tons/100 days = 2.5 tons/day, the amount of ^{239}Pu bred per ton of natural uranium was

$$\frac{\text{Bred Pu-239}}{\text{Natural uranium}} \approx \frac{0.19\text{ kg/day}}{2.5\text{ tons/day}} \approx 0.076\ \frac{\text{kg}}{\text{ton}} \tag{8.3}$$

Note that the amount of fissionable ^{239}Pu produced from a ton of natural uranium is roughly 100 times smaller than the maximum amount of fissionable ^{235}U (7.2 kg) that could be extracted from that same ton of natural uranium via the enrichment methods of the previous section. Again, this low level of production is due to the need to avoid creating much ^{240}Pu in the fuel. As a result, a fission fuel breeding program would use ∼100 times more uranium than a fission fuel enrichment program (unless the irradiated uranium were reused in the breeder reactor after the plutonium had been removed, which may or may not have been practical under the urgent pressures of the war).

Counterbalancing that disadvantage is the advantage that a breeder reactor and the accompanying chemical purification processes handle fission fuel in a very dense solid or liquid state, whereas enrichment methods handle fission fuel in a far less dense gaseous or plasma state. Therefore the equipment for breeding would be much more compact, and could potentially be built and operated by fewer people, than the equipment for enrichment.

As long as the reactor is large enough to have a self-sustaining fission chain reaction, these characteristics can be scaled up or down in a linear fashion, using the approximate numbers in Table 8.4 as a basis for reference [Kemp 2005]. For example, if each Hanford reactor held 250 tons of natural uranium and produced approximately 69 kg of ^{239}Pu per year, a hypothetical German reactor holding approximately 22 tons of natural uranium could produce approximately 6 kg of ^{239}Pu per year, enough for one full-sized ∼20 kiloton implosion bomb (like the U.S. Gadget and Fat Man bombs) per year. From Eq. 8.3, producing 6 kg of plutonium would require processing approximately 79 tons of uranium.

Characteristic	**Approximate value (scales linearly)**
Thermal power	25 MW
Reactor core volume	100 m^3
Moderator	150 tons of graphite, or 80 tons of heavy water, or some of both
Natural uranium in reactor	25 tons
Replace uranium every	100 days
Uranium consumption rate	91 tons/year
Plutonium production rate	6.9 kg/year
Cost (1940s U.S. dollars)	$6,000,000

Table 8.4: Approximate characteristics of a breeder reactor for producing ^{239}Pu.

^{232}Th is useful for breeding ^{233}U but cannot sustain a fission chain reaction on its own. The reactor would need to contain natural uranium or uranium enriched in ^{235}U. On the order of $\sim$90% of the neutrons from the uranium would be needed to sustain the chain reaction, so only $\sim$10% of the neutrons could be spared to breed ^{233}U from ^{232}Th, and hence only $\sim$10% of the total fuel in the reactor could be thorium. Thus a fission reactor for breeding ^{233}U might be $\sim$10 times larger in volume or mass than a reactor for breeding ^{239}Pu. (Of course, plutonium would also be bred within the $\sim$90% of the reactor fuel that was uranium, and that plutonium could be extracted as well.) For this reason, it seems likely that the German nuclear program would have generally preferred producing ^{239}Pu instead of ^{233}U, although scientists may have certainly tried ^{233}U (especially because of the large amount of thorium that was available to the German nuclear program).

Many highly radioactive isotopes with short half-lives are created when fuel is bombarded with neutrons in a fission reactor, so it is customary to let the fuel "cool off" for a month or so after being removed from the breeder reactor before it is processed by people. Since the German nuclear program would have had a great sense of urgency and likely did not value the lives of its low-level workers, it might have processed irradiated fuel with a much shorter cooling off period.

There is some evidence that Germany developed chemical reprocessing methods to extract and purify the bred ^{239}Pu or ^{233}U (p. 3826). Although it is currently unknown just how far that work progressed during the war, or in what geographic locations, the scientific details of reprocessing constrain where and how it could have been done, and may guide historians in locating relevant documents and geographic sites:

- Due to the relatively sophisticated chemistry involved in reprocessing (p. 5135) and the fact that it would be tied to secret weapons development, it seems probable that any such reprocessing would have been run by I.G. Farben, or at the very least would have intimately involved I.G. Farben.

- Because of the large amount of irradiated uranium or thorium fuel that would need to be processed for a much smaller amount of ^{239}Pu or ^{233}U, and because of the great personal danger involved in exposure to the associated high levels of radiation and toxic chemicals, it also seems likely that any such work in wartime Germany would have involved slave labor and high fatalities (at least if it advanced beyond small-scale proof-of-concept laboratory experiments).

- Because of the large amount of material to be processed and the extreme danger in handling it, chemical reprocessing would probably have been conducted at or near the fission reactor(s) or electronuclear breeding site(s) where the ^{239}Pu or ^{233}U was bred.

- For cooling of the fission reactor and for both cooling and chemical steps during reprocessing, a breeding/reprocessing facility would likely be located very close to an abundant source of fresh water.

Tritium could also be bred from lithium and/or heavy water by neutron bombardment in a fission reactor. Tritium would be very useful for fusion boosting of fission bombs and/or for hydrogen bombs (Section 8.8.9).

8.8.6 Electronuclear Breeding of ^{239}Pu and/or ^{233}U

Even without a fission reactor, it is possible to produce significant amounts of ^{239}Pu or ^{233}U via electronuclear breeding (Section D.6). In this process, a particle accelerator fires a beam of high-energy charged particles (typically protons, deuterons, or electrons with a kinetic energy of many millions of electron-volts or MeV) at a target containing ^{238}U or ^{232}Th. When those energetic charged particles strike the nuclei of the target material, they knock some neutrons free; those neutrons are absorbed by the ^{238}U to become ^{239}Pu, or by ^{232}Th to become ^{233}U, as shown in Eqs. (8.1)–(8.2). In more sophisticated and efficient systems, the target may also contain an initial layer of lithium or beryllium atoms, which are especially good at releasing neutrons when struck by high-energy charged particles. If furthermore the target is immersed in a neutron moderator (such as heavy water or pure graphite) and surrounded by a neutron reflector (such as beryllium), each neutron that is originally generated can lead to a cascade of several more neutrons by subcritical fission reactions, yielding several atoms of bred fuel per charged particle in the beam. If the target is lithium without uranium or thorium, electronuclear breeding can be used to produce tritium.

Electronuclear breeding was seriously pursued by the United States and other countries after World War II, and even now is of concern as a proliferation risk for how new countries could produce nuclear weapons.[15]

Archival documents show that in German-controlled areas from the Netherlands to Czech territory, a considerable number of high-energy particle accelerators were produced and used as high priorities during the war. Rolf Wideröe (Norwegian but studied and worked in Germany, 1902–1996), Max Steenbeck (German, 1904–1981), Walter Dällenbach (Swiss, 1892–1990), Walther Bothe (German, 1891–1957), and many others worked to design, build, and test the accelerators (pp. 3020–3091, 3954–4022, 4504–4510).

Purely scientific research would not have been sufficient justification for all of the funding, labor, and materials that went into these accelerators when war needs and shortages were so dire. While accelerators would certainly be useful for measuring fundamental nuclear properties that are relevant to designing nuclear reactors and bombs, one or two modest accelerators would have been sufficient for that purpose. Indeed, Germany already had access to the Joliot-Curie cyclotron in Paris for such measurements.

Most of the accelerators appear to have been closely linked with the German nuclear weapons program and treated as a high priority for that program until the very end of the war. Electronuclear breeding seems to be the best explanation.

In August 1945, after some nuclear-related censorship of the U.S. press had been lifted, newspapers belatedly reported that sabotage and U.S. bombing had delayed German nuclear weapons work in Czech territory, probably a reference to cyclotrons that were produced there: "A shattering American air raid, Czech sabotage and an accident frustrated German experiments in Czechoslovakia seeking to develop an atomic bomb, newspaper accounts said here today" (p. 3979).

---

[15] Barashenkov et al. 1987; Barber and George 1959; Chichester 2009; Kemp 2005; Livdahl 1981; Magill and Peerani 1999; Riendeau et al. 1999; Van Atta 1977.

In November 1945, *Time* magazine reported evidence of secret wartime German work to mass-produce cyclotrons in Czech territory for a nuclear weapons program (p. 3987).

In May 1945, the Soviet physicist Georgy Flerov was sent by Joseph Stalin and Igor Kurchatov to investigate the German nuclear program. In 1983, Flerov described his interrogation of a German cyclotron expert who had been captured by Soviet forces at the end of the war. The German physicist told of at least one highly secret underground SS/Reichspost installation in the Riese complex in Silesia that was using multiple cyclotrons for urgent war-related work—most likely electronuclear breeding (p. 4504).

Werner Grothmann, Heinrich Himmler's chief adjutant, independently confirmed that there was a high-priority, highly secret, joint SS/Reichspost program to breed plutonium without a reactor—electronuclear breeding—in underground installations using particle accelerators that had been manufactured in Czech territory and in Austria (p. 4024).

Simple physics calculations (pp. 5133–5134) demonstrate that electronuclear breeding of kilograms of ^{239}Pu or ^{233}U for a fission bomb, or tens of grams of tritium for fusion boosting a bomb, would potentially have been quite feasible (though technically challenging) for the wartime German program.[16] Of course, any ^{239}Pu or ^{233}U created via electronuclear breeding would still have needed to be chemically extracted from the target material, just as with breeding in a fission reactor (p. 5135).

It is important for historians to search for more evidence of a wartime electronuclear breeding program (both in archival documents and at physical sites that may have been involved in this work), and to ascertain just how far any such electronuclear program actually progressed during the war.

---

[16] ^{237}Np fission fuel [Sanchez et al. 2008] could also have been bred using accelerators (e.g., by knocking a neutron out of ^{238}U), although it probably would have been more difficult to produce in quantity than ^{239}Pu or ^{233}U [Benedict et al. 1981].

8.8.7 Production of Other Potentially Nuclear-Related Materials

During the war, Germany produced large quantities of materials that had non-nuclear applications, yet would also have been extremely useful for a nuclear weapons program (Section D.7). From archival documents that are currently available, it is not possible to determine whether or how much of each material was used for nuclear applications, but clearly the materials were readily available if some quantity of them had been requisitioned by a high-priority nuclear program.

Any nuclear-related production programs in wartime Germany would have had access to a larger labor pool than comparable programs in the United States. The population of the greater German-speaking world was equal to or somewhat greater than that of the United States at the time (Section 10.1.1). Including the populations of countries that were allied with or occupied by Germany, the total population of German-controlled territory was far larger than that of the United States.

Likewise, the gross domestic product (GDP, a measure of economic and industrial resources) of German-controlled territory was roughly comparable to or by some measures even greater than that of the United States (pp. 2100–2101).

Just as importantly, the electrical power production of German-controlled Europe was fairly comparable to or even greater than that of the United States (pp. 2100–2104). Germany had access to power plants and fuel sources throughout most of Europe, and also built more during the war (e.g., pp. 3755–3759), so energy would not have been a limiting factor for nuclear-related production.

Deuterium can serve as a great fusion fuel and source for producing neutrons and tritium, and an excellent neutron moderator for fission reactors when in the form of deuterated (heavy) water. According to official histories, heavy water was only produced in significant quantities at the Norsk Hydro hydrogen factory in Vemork, Norway, which was famously attacked by Allied forces and the Norwegian Resistance and forced to shut down. In fact, documents indicate that heavy water production facilities for the German nuclear program were known or reported to be located at sites all over German-occupied Europe (see map on p. 4030):

1. Vemork, Norway (pp. 4031–4039).
2. Såheim, Norway (p. 4040).
3. Notodden, Norway (p. 4041).
4. I.G. Farben Leuna Werke, low-pressure production plant (pp. 4042–4050).
5. I.G. Farben Leuna Werke, high-pressure production plant (pp. 4042–4050).
6. I.G. Farben Bitterfeld (pp. 4050–4051) [Karlsch 2005, p. 110; Sadovsky 2011b].
7. I.G. Farben Halle (pp. 4052–4055).
8. Kiel, probably adjacent to the Deutsche Werke Kiel (pp. 4056–4061).
9. Dräger Werke, Lübeck (pp. 4062–4063).
10. Müggenberg (pp. 4064–4065).
11. Chemische Fabrik Griesheim-Elektron, Frankfurt am Main (pp. 3678–3680, 4066–4067).

12. Berlin plant (p. 4068).
13. Linde plant, Munich (p. 4068).
14. Montecatini plant, Sinigo-Merano, Italy (p. 4069).
15. Montecatini plant, Cotrone/Crotone, Italy (p. 4069).
16. I.G. Farben Auschwitz in Poland (pp. 4069, 4452).
17. Plant near the Schmiedeberg (now Kowary, Poland) uranium mine (p. 4069).
18. Plant near Breslau (now Wrocław, Poland; pp. 4070–4071).
19. Weer, near Wattens, Tyrol, in the Austrian Alps (pp. 4072–4077).
20. B9 Quarz underground complex near Roggendorf and Melk, Austria (p. 4078–4079).
21. Degussa plant at Rheinfelden, Austria (pp. 4080–4081).
22. Austrian Chemical Works plant at Weissenstein, Austria (pp. 4080–4081).
23. Siemens and Halske plant in Lehesten (pp. 3689, 3696, 4080).
24. Bayrische Stickstoffwerke in Piesteritz (pp. 4082, 4452–4453).
25. Pardubice/Wesser, Czechia (pp. 3446, 4082–4083).
26. Other possible locations (pp. 4084–4086).

Thus Germany was producing large quantities of heavy water in a very determined fashion at numerous plants all over Europe, despite the difficulties of Allied bombing and the urgent wartime needs to produce other materials and products. The existence of this massive, high priority, highly secretive heavy water production program strongly suggests that one or more fission reactors may have actually been operational during the war. At the very least, it seems to indicate that Germany was trying to get reactors operational as soon as possible. Germany may have also needed significant quantities of deuterium/heavy water for electronuclear breeding of fission fuel and/or for fusion fuel production.

Lithium was utilized for processing ceramics, glass, and metals, but it would also have been extremely useful for producing tritium, neutrons, and/or fusion reactions. Germany produced hundreds of tons of lithium and lithium compounds during the war (p. 4090). Alfred Klemm developed methods to separate the naturally occurring ^{6}Li and ^{7}Li isotopes, which would have been required only for nuclear applications (pp. 4344–4347). Klemm also knew of work on tritium being conducted by other scientists (p. 4346).

High-quality graphite was widely used for high-temperature exhaust steering rudders on the A-4 (V-2) and other rockets, and was utilized for making electrodes, filters, and other components too. However, graphite could also have been quite useful as a neutron moderator to slow down neutrons and promote chain reactions in a fission reactor. Germany produced many tens of thousands of tons of graphite during the war (p. 4110).

While some historians have claimed that the German nuclear program was unwise to choose heavy water instead of graphite as a reactor moderator, the actual historical and scientific record suggests otherwise.

First of all, it is far from certain that the German program did exclude graphite. For example, I.G. Farben's Bitterfeld facility was mass-producing both graphite (p. 4110) and heavy water (p. 4050) as well as other nuclear-related materials (pp. 4128, 4133, 4136). Similarly, Griesheim plants were producing both graphite (pp. 4114–4116) and heavy water (pp. 4066–4067), with other nuclear-related facilities such as Degussa in the same area [Hayes 2004; Nagel 2016]. Graphite was also mass-produced at the Siemens Plania Werke in Racibórz/Ratibor, Poland (pp. 4110–4114), near a reported heavy water plant at Auschwitz (pp. 4069, 4452) and reported uranium enrichment plants at Opava and Ostrava (p. 3749).

It may well be that the German program was aware that graphite could be used as a moderator but preferred heavy water for several reasons:

- The "moderating ratio," the ratio of how strongly a moderating material slows down neutrons vs. how strongly it absorbs neutrons, is ∼25–100 times larger for heavy water than for graphite (depending on the purity of the heavy water). Since heavy water is far more effective than graphite at slowing neutrons without absorbing them, much less moderator and/or natural uranium would be required for a reactor to achieve criticality, or the reactor could be more easily loaded with other neutron-absorbing materials such as lithium for tritium production. Because of these advantages, the United States built five heavy water reactors at the Savannah River Site in the 1950s and used them to breed over 36,000 kg of plutonium during the Cold War.[17]

- Using heavy water would avoid "Wigner's disease," in which irradiated graphite swells, stores/releases large amount of energy, and creates problems in a reactor, as caused major headaches in both the United States (diagnosed by Eugene Wigner) and the Soviet Union (e.g., the January 1949 Chelyabinsk Reactor A accident that shortened Igor Kurchatov's life) [Kojevnikov 2004, p. 151; Bruce Cameron Reed 2019, pp. 260–261; Rhodes 1995, p. 277].

- Graphite is flammable and could cause or contribute to a catastrophic reactor accident, as in the 1957 Windscale reactor fire in the U.K. nuclear weapons program [Lorna Arnold 2007; Mahaffey 2014, p. 176].

- While being used as a moderator for fission reactions, heavy water will simultaneously breed tritium. Further tritium can be bred by inserting lithium into the heavy water reactor (which can spare more neutrons for that purpose than a graphite reactor could, since the moderating ratio of heavy water is much higher). For example, the five heavy water reactors at the U.S. Savannah River Site produced around 200 kg of tritium during the Cold War [Høibråten 2020]. There is evidence that the wartime German program wanted fusion fuels such as tritium for (a) neutron initiators in fission bombs, (b) fusion neutron boosting in fission bombs, and (c) fusion fuel for a megaton-level H-bomb (Section D.9).

- Using heavy water for reactors would leave all of Germany's graphite available for other urgent applications, such as electrodes, rocket exhaust steering rudders, and steel production.

https://nucleus.iaea.org/sites/graphiteknowledgebase/wiki/Wiki%20Pages/Nuclear%20Properties.aspx

Beryllium was used for producing certain metal alloys, but it also could have been quite useful as a neutron reflector and multiplier in a fission reactor, electronuclear breeding system, or fission bomb. Wartime production of beryllium was in the tons (p. 4096).

Boron was needed for producing certain types of glass, ceramics, and metals, but it also would have been very useful as a neutron absorber. Large quantities of boron were produced in wartime Germany (p. 4104).

Fluorine was used for various industrial chemical production processes, but it also would have been essential for producing uranium hexafluoride for the enrichment of ^{235}U. Wartime production of fluorine was in the thousands of tons (p. 4118).

Aluminum was employed for fabricating a wide variety of metal structures and packaging. On the other hand, aluminum could have been quite useful as cladding around fission fuel in a reactor, or as spherical pusher and casing shells in a fission bomb as described in Section 8.8.8. Thousands of tons of aluminum were produced in wartime Germany (p. 4126).

Calcium was used in making certain metal alloys, but it also would have been extremely useful in key steps of the purification of thorium, uranium, and/or plutonium. Germany produced thousands of tons of calcium during the war, and is even documented to have utilized calcium to purify thorium and uranium (p. 4132).

Nickel was needed for nickel-cadmium batteries and certain alloys. Yet because nickel is much more resistant than other metals to corrosion by uranium hexafluoride (used in uranium enrichment), it would have been invaluable in a nuclear program. Wartime production of nickel was many thousands of tons (p. 4138).

Zirconium was used for high-temperature metals and ceramics in non-nuclear applications, but its high temperature resistance and other properties also would have made it ideal as a fuel cladding material in fission reactors. Tons of zirconium were produced in wartime Germany. There was also an apparently related story about the SS *Flying Enterprise*, which sank on 10 January 1952 while carrying cargo from Hamburg to the United States. Its captain, Kurt Carlsen, later told interviewers such as Bjarne Bekker that the cargo included five tons of zirconium, left over from the wartime German nuclear program, which was salvaged from his sunken ship and used in the first U.S. nuclear submarine, USS *Nautilus* (p. 4142).

Cadmium was important for nickel-cadmium batteries and soldering, but it also could have been extremely useful as a neutron absorber. Germany produced thousands of tons of cadmium during the war (p. 4148). Germany also possessed methods for electroplating thin layers of materials such as cadmium onto aluminum. Such methods are potentially quite relevant for creating a neutron-absorbing cadmium layer on a spherical aluminum pusher as in the German fission implosion bomb described in March 1945 (Section 8.8.8).

Some sites were producing multiple nuclear-related materials at the same location. For example, I.G. Farben's Bitterfeld facility is documented to have been producing heavy water (p. 4050), graphite (p. 4110), aluminum (p. 4128), and calcium (pp. 4133, 4136); Bitterfeld may have produced other relevant materials as well.

Intriguingly, significant quantities of many of these nuclear-related materials were also shipped to Japan, Germany's wartime ally, along with at least 560 kg of (possibly enriched) uranium and other cutting-edge military technologies (pp. 4094, 4103, 4858–4892).

8.8.8 Fission Bomb Designs

A number of independent sources provided information about wartime German fission bomb designs (Section D.8).

No later than 1940, the mathematicians Walter Hantzsche (German, 19??–19??) and Hilmar Wendt (German, 1913–19??) derived pressure, density, and temperature solutions that are applicable to spherical and cylindrical implosion bomb configurations, and that are still used today (pp. 4166–4169).

No later than 1942, Gottfried Guderley (German, 1910–1997), a hydrodynamics expert working for the German military, performed very similar calculations for spherical and cylindrical implosions (pp. 4170–4171).

As already noted in Section 8.8.4, a 1943 U.S. intelligence report stated that "several factories and hundreds of workers" in underground facilities near Lüneburger Heide were producing a special new type of explosive that was so energetic that one kilogram of the new material would have a blast radius of several kilometers, and that would be placed into bombs of a highly unusual spherical design (p. 4176).

In November 1944, *Time* magazine published a news report that Germany was developing a fission bomb with a spherical implosion design. The implications of the article were so clear that Leslie Groves, the military leader of the Manhattan Project, had a strong reaction when he found out (p. 4185).

A 23 March 1945 letter from General Ivan Ilyichev, chief of intelligence for the Soviet army, to Joseph Stalin reported that the Germans had an atomic bomb and described it in considerable detail as a 2-ton, 1.3-meter-diameter spherical implosion device with multiple concentric layers and a ^{235}U core (Fig. 8.32, Table 8.5, and Section 8.8.12).

Erich Schumann (German, 1898–1985), the Heereswaffenamt's head physicist, was an expert on shaped-charge explosives and X-ray diagnostics for explosives, Wernher von Braun's Ph.D. thesis advisor for the development of rockets, and a key figure in Germany's biological warfare program and other advanced research programs. No later than 1940, he, Walter Trinks (German, 1910–1995), Rudi Schall (German, 1913–2002), and others began investigating the use of shaped-charge explosives (especially spherical, but also other geometries) and explosive lenses to generate implosive shock waves strong enough to initiate fission and fusion reactions and produce a large nuclear explosion, and Schumann continued to advance that work throughout the war. Schumann filed approximately 40 secret patents on this work during the war, which ultimately led to several unclassified postwar patents. Those published patents described designs extremely similar to the design that Ilyichev said was tested in March 1945: spherical implosion bombs with a total mass of approximately 2 tons, an outer layer of segmented explosive lenses, inner spherical layers of cadmium, uranium, and other materials, and fusion fuel in the center (pp. 4187–4255). (Since the United States possessed much of this evidence, one must wonder why Samuel Goudsmit knowingly gave false testimony to the U.S. Senate by claiming that Schumann was mainly just interested in "the physics of piano strings"—see pp. 3294–3297, 3301.)

In November 1945, the German economist Erwin Respondek wrote that Erich Schumann had been involved in the development of an atomic bomb that used uranium fuel and a neutron initiator (and apparently Schumann's expertise, conventional explosives for spherical implosion), and that the problem was "solved" in 1944 (p. 4194).

Adolf Busemann (German, 1901–1986), Rolf Engel (German, 1912–1993), Hubert Schardin (German, 1902–1965), and others also played major roles in the development of implosion bombs [Karlsch 2005; Krehl 2009].

A Top Secret U.S. cable from March 1946 stated that a "capable young engineer" in Poland knew that atomic bomb casings included a layer of cadmium, which was true for the implosion bomb designs described by both Ilyichev and Schumann (p. 4255).

1946 U.S. intelligence documents described how SS General Hans Kammler's deputy Erich Purucker and a car full of German atomic bomb plans were captured by Russian forces in May 1945 (p. 4914).

After the war, Kurt Diebner discussed spherical implosion bomb designs, specifically showing a hollow spherical pit of fission fuel with fusion fuel in the center, likely based on the wartime work in which he had participated (pp. 4260–4267).

German witnesses described secretive and mysterious work that had been conducted during the war to produce and test nesting aluminum spheres that apparently matched the description of those in the implosion bomb designs (p. 4270).

Werner Grothmann recounted the development of an atomic bomb that "possessed a spherical shape with a diameter of over one meter. It was very heavy, even though the bomb body itself was supposed to be out of aluminum. It was said, if one reduces the weight, the yield is not as high" (pp. 4271–4273).

All of these independent sources appear to have been describing the same spherical implosion fission bomb design, or very closely related variations of the same basic design. Their details have been correlated and compared with fundamental physics and unclassified documents about the first U.S. implosion bombs (Gadget, tested in New Mexico on 16 July 1945, and its fully packaged version, Fat Man, dropped on Nagasaki on 9 August 1945) and other nuclear weapon designs.[18] Based on this information, approximate design parameters have been calculated for the German spherical implosion bomb, specifically the version that Ilyichev reported was tested in Thuringia in March 1945. The results are summarized in Table 8.5. For much more information, see Section D.15.5.

The implosion design described by Ilyichev and the other sources seems very detailed, physically feasible, and deeply grounded in experimental and engineering details. While similar to the U.S. Gadget/Fat Man, it does not appear to be a carbon copy of that design, suggesting that it was arrived at independently and not by any German espionage of the U.S. program. In fact, in some respects the German design was several years more advanced than U.S. designs. The German design seems to have been far more than an abstract concept that was never reduced to practice, or a hasty idea that was thrown together at the end of the war. It appears to have been the end product of a well-funded, long-running, highly scientifically skilled nuclear weapons development program.

Наш достоверный источник из Германии сообщает:

"Немцы в последнее время произвели два взрыва бомбы большой мощности в Тюрингии. Взрывы проводились в лесной местности в обстановке строжайшей секретности. От центра взрыва деревья повалены на расстоянии 500-600 метров. Уничтожены специально построенные для опытов укрепления и сооружения. Находящиеся в центре взрыва военнопленные пог

Figure 8.32: Examples of some of the evidence for the development of a fission implosion bomb in wartime Germany. Above: Erich Schumann's schematic design for a spherical implosion bomb (Section D.8). Below: the beginning of a March 1945 Soviet intelligence report giving Joseph Stalin details about successful German tests of a fission implosion bomb (Section D.12).

Component	Gadget/Fat Man	Thuringian Device
Neutron initiator	$\sim$ 7 g beryllium/polonium-210 "urchin" 1.25 cm radius	Deuterium + lithium with high voltage $\sim$ 1.25 cm radius and/or external 6 MeV betatron
Pit	6.2 kg ^{239}Pu 4.6 cm radius	**For test:** <1 kg inner layer of ^{235}U with $\sim$ 5–10 kg natural or low-enriched U outer layer **For deployment:** $\sim$ 5–10 kg ^{235}U $\sim$ 5 cm radius
Tamper/ reflector	108 kg natural U 11.1 cm radius	$\sim$ 100 kg natural U $\sim$ 11 cm radius
Neutron absorber	Boron-10 plastic 3.2 mm thick	$\sim$ 1.3 kg cadmium $\sim$ 1 mm thick
Pusher	130 kg aluminum 23.5 cm radius	$\sim$ 130 kg aluminum $\sim$ 23 cm radius
Explosive	Composition B and baratol 2500 kg, segmented $\sim$ 70 cm radius	TNT, RDX, and liquid oxygen $\sim$ 1400 kg, segmented $\sim$ 63 cm radius
Explosive case	$\sim$ 180 kg aluminum 72.5 cm radius	$\sim$ 140 kg aluminum $\sim$ 64 cm radius
Ballistic case	Steel 4.5 mm thick 75 cm radius	$\sim$ 190 kg steel $\sim$ 4.5 mm thick 65 cm radius
Overall radius	75 cm	$\sim$ 65 cm
Total mass	3000 kg (bomb only) 4670 kg (with shell and fins)	$\sim$ 2000 kg
Delivery system	Boeing B-29 heavy bomber	A-4, A-9, or A-9/A-10 ballistic missile
Explosive yield	20 kilotons	**For test:** < 1 kiloton **For deployment:** $\sim$ 5–100 kilotons

Table 8.5: Comparison of the U.S. Gadget/Fat Man implosion design (from unclassified sources) with extrapolated design parameters of the March 1945 Thuringian device (Section D.15.5). The explosive yield of the German design was highly dependent on how much fission and fusion fuel were used.

Neutron initiator. A neutron initiator provides neutrons to start a fission chain reaction at the optimal time during implosion. Gadget/Fat Man used a crude polonium-210/beryllium "urchin" initiator that produced $\sim 2 \times 10^8$ neutrons/sec when crushed at the center of the bomb [Reed 2019, p. 305]. Ilyichev and other sources reported that the neutron initiator at the center of the German bomb used fusion fuel (e.g., deuterium + lithium) stimulated by high voltage (similar to the high-voltage fusion neutron initiators used by modern nuclear weapons). During the final two years of the war, the C. H. F. Müller company in Hamburg produced and delivered at least five high-voltage fusion neutron generators that produced up to 2×10^{11} neutrons/sec, 1000 times higher than the U.S. urchin (pp. 3963, 4318). Hans Ritz, the managing director of C. H. F. Müller, told Allied investigators in May 1945 that his company's work was important for nuclear weapons (pp. 4318–4320). A Dutch physicist told postwar Allied investigators that "the S.S. placed high importance on obtaining neutron generators" from Müller and other suppliers for secret "new weapons" (p.

4314). After the war, Kurt Diebner patented a high-voltage fusion neutron initiator at the center of an implosion bomb (pp. 4260–4261).

In addition to serving as a neutron initiator, the fusion fuel at the center of the German bomb design could have caused significant fusion boosting of the explosive yield of the bomb. Fusion reactions produce copious neutrons, which would promote many fission reactions in the surrounding pit, greatly increasing the number of fission reactions and hence the yield before the bomb flew apart and the reactions stopped. Fusion boosting was not even tested by the United States until the Greenhouse Item test in 1951 [https://nuclearweaponarchive.org/Usa/Tests/Grnhouse.html]; it is now commonly used in nuclear weapons.

Ilyichev also referred to a second neutron initiator: an external compact betatron directing electrons with energies of at least 6 MeV toward the center. The $\geq$6 MeV electrons would produce $\leq$6 MeV gamma-ray photons in the uranium via bremsstrahlung and other absorptive processes, the photons would induce photofission reactions in the uranium, and neutrons would be released. This second neutron initiator would have further increased the number of initial neutrons and hence the yield. It also would have served as a backup initiator in case the fusion neutron initiator failed to fire at the right time. Several manufacturers produced betatrons during the war; in particular, Siemens-Reiniger in Erlangen built compact 6-MeV and 7-MeV betatrons. The United States did not use a betatron as a neutron initiator in a bomb until the George test of Operation Tumbler-Snapper in 1952 (pp. 3088–3089, 3957–3970, 5160).

Pit. Ilyichev described the pit of the Thuringian device as a hollow sphere of ^{235}U that was imploded to achieve criticality. Gadget/Fat Man used a hollow spherical pit with 6.2 kg ^{239}Pu. Since the Thuringian device appears to have been fairly comparable in overall size and design, it seems reasonable to assume that it could have accommodated a pit of up to 5–10 kg of ^{235}U. Much less ^{235}U may have been used in the test explosions, especially if the central fusion fuel provided a significant number of neutrons. Multiple independent sources appear to have mentioned the wartime German production of fission pits with masses between 1 and 8 kg (pp. 3350–3351, 3827–3830, 4176, 4183, 4207–4210, 4411, 4564, 4635–4639, 4903).

Tamper/reflector. Ilyichev listed a "delay mechanism" between the "sphere made of metal uranium 235" and the aluminum "protective casing." Gadget/Fat Man used a 108 kg natural uranium tamper between the pit and the aluminum pusher to "delay" the expansion of the fissioning center and to reflect escaping neutrons, thereby increasing the yield. The German tamper probably also used around 100 kg of natural uranium. Elsewhere in his report, Ilyichev appears to have simply lumped the uranium pit and uranium tamper together in describing the inner part of the bomb as being "filled with uranium." Uranium metal was available from suppliers such as Auergesellschaft, Degussa, Buchler, and Treibacher.

Pusher. Ilyichev stated: "The uranium sphere is encased in a protective aluminum casing." Gadget/Fat Man used a 130 kg aluminum "pusher" between the conventional explosive and the uranium reflector/tamper. Because the aluminum pusher's density was higher than that of the explosive but lower than that of the uranium, the pusher helped to efficiently transfer the implosive shock wave from the explosive to the uranium. The Thuringian device apparently used the same approach. The wartime German aluminum industry was enormous and highly capable, and witnesses described secretive work that had been conducted during the war to produce and test nesting aluminum spheres closely resembling the description of those in the implosion bomb designs (pp. 4126–4131, 4270).

Neutron absorber. Ilyichev, Schumann, and the "capable young engineer" in Poland mentioned a layer of neutron-absorbing cadmium to prevent stray neutrons from initiating fission reactions in the core at the wrong time. Gadget/Fat Man used a layer rich in boron-10 for that same purpose. Wartime German companies such as Kampschulte, Blasberg, and Wilhelm Meyer did electroplating of aluminum components, including electroplating with cadmium, and would have been capable of producing a cadmium-electroplated aluminum pusher (pp. 4148–4152).

Explosive. Ilyichev said the Thuringian device used specially shaped segments of TNT, although that might mean any of several TNT-related explosives that were widely produced by Germany during the war. Erich Schumann and Walter Trinks demonstrated a sophisticated knowledge of TNT, hexogen/RDX, other explosives, and explosive lenses using combinations of those materials. Schumann and his colleagues began working on explosive lenses no later than 1940, and by 1942–1943 they were testing large explosive lenses (pp. 4211–4219). Based on information from Ilyichev, Schumann, and Trinks, the explosive layer's mass appears to have been approximately 1400 kg.

TNT molecules ($C_7H_5N_3O_6$) contain relatively few oxygen atoms and normally release their explosive energy by decomposing into a number of smaller oxygen-deficient molecules. Without providing added oxygen, detonation releases 4.184 GJ of energy per ton of TNT. If enough liquid oxygen were provided, detonation could release up to 14.5 GJ per ton of TNT. Thus with liquid oxygen, the $\sim$1400 kg of explosives in the Thuringian device could easily have been quite comparable to or even significantly more powerful than the 2500 kg of explosives in the Gadget/Fat Man design.

Explosive case. According to Ilyichev: "TNT is covered by a protective layer made of a light aluminum alloy." If the aluminum explosive case had an outside radius of $R = 64$ cm (just smaller than Ilyichev's quoted radius for the outer steel case), a thickness of 1 cm, and a density of 2.70 g/cm^3, its mass would have been approximately 140 kg.

Ballistic case. Ilyichev stated: "An exterior casing of armored steel is installed above the blasting mechanism." Steel alloys have densities in the range of 7.75–8.05 g/cm^3, so one may use an average density of 7.9 g/cm^3. If the Thuringian device had a steel ballistic case with an outside radius of $R = 65$ cm and the same thickness as Fat Man's case (0.45 cm), the mass of the case would have been approximately 190 kg.

Total mass. The component masses for the Thuringian device in Table 8.5 add up to a total mass of approximately 2000 kg, just as Ilyichev and Schumann reported. Thus the German bomb had a total deployed mass less than half that of the first U.S. fission bombs (4670 kg for Fat Man), yet could have had a comparable or even greater yield.

Smaller version. In addition to the two-ton spherical fission implosion bomb described above, several sources discussed the wartime development of a smaller fission bomb. It was described as a tactical, nonspherical, two-point-ignition, fission implosion bomb that was externally similar to a standard German 250 kg bomb, had a full yield likely less than one kiloton, and was potentially ready for deployment (pp. 4246–4248, 4271–4277, 5030).

Delivery vehicles. It took the United States several years to reduce the size and mass of fission bombs from its initial Fat Man and Little Boy designs. According to dozens of independent sources (p. 5821), the German fission bombs were intended to be launched on a rocket; the United States was not prepared to do that until 1958 (after extensive help from hundreds of German-speaking scientists and engineers it had acquired). During the war, jet bombers and submarine-launched missiles were also under development as delivery vehicles for the fission bombs (p. 5820).

8.8.9 Hydrogen Bomb Designs

Wolfgang Ferrant (German?, ??–??), Ulrich Jetter (German, 1914–??), Alfred Klemm (German, 1913–2013), Karl Lintner (Austrian, 1917–2015), Josef Mattauch (Austrian, 1895–1976), Erich Schumann, Georg Stetter (Austrian, 1895–1988), Walter Trinks, and many others worked in teams that researched and produced significant amounts of fusion fuels and potential methods to use them (Section D.9).

German patents, articles, and other documents from 1933 through 1945 discussed how to produce fusion reactions in high-voltage tubes (pp. 3958–3970 and 4281–4327). That technology would have been very useful as a fusion neutron initiator in a fission bomb, as described by Kurt Diebner (p. 4261) and Ivan Ilyichev (p. 4485).

In postwar papers apparently based on wartime work, Erich Schumann and Walter Trinks (pp. 4187–4255) and Kurt Diebner (pp. 4260–4267) described spherical implosion bomb designs with a center of fusion fuel inside a spherical shell of fission fuel. That "fusion boosting" approach could have greatly increased the yield of a fission bomb by supplying far more neutrons to induce fission reactions.

A number of documents show that there was wartime work using lithium and deuterium together as fusion fuel (pp. 4305–4341). Because lithium deuteride is solid and not a gas or cryogenic liquid, it makes an ideal fuel for hydrogen bombs.

During the war, Alfred Klemm (under the direction of Josef Mattauch) perfected a method to separate the lithium-6 isotope from the predominant lithium-7 in natural lithium (pp. 4344–4347). That would only be useful for nuclear applications. Klemm also stated that there was wartime work to produce tritium, another very potent fusion fuel (p. 4346).

In 1950, Ulrich Jetter (German, 1914–??) published a detailed proposal that fusion bombs could use lithium-6 deuteride as readily storable solid fuel, rather than the much more troublesome cryogenic deuterium and tritium (p. 4348). Based on the other documents available, Jetter's description appears to be directly based on wartime German work. According to conventional histories, lithium-6 deuteride was first considered in the United States by Edward Teller in 1947 and in the Soviet Union by Vitaly Ginzberg in 1949, was first tested by the United States in 1954, and is commonly used in modern H bombs.[19]

In 1946, several scientists and engineers reported that during the war, Germany had been working on a 6-ton radioactive bomb, as well as methods to deliver it by rockets or aircraft (pp. 4338, 4350–4363, and 5343). Such a massive bomb would have been very challenging to deliver, and could presumably only have been justified if it were a hydrogen bomb. Conventional explosives, a "dirty bomb" of conventional explosives with radioactive material, chemical weapons, biological weapons, and even fission bombs could have been packaged into much smaller and much more easily deliverable sizes (and if necessary, several of them could have been delivered separately to the same target).

A 1946 U.S. intelligence document mentioned wartime German research on H-bomb development as well as nuclear-armed ballistic missiles (p. 4368).

In 1944–1945, several independent sources reported that Germany was developing a bomb with a six-mile blast radius, which is characteristic of the several-megaton energy of an H bomb, in stark contrast to the much smaller several-kiloton energy of a plain fission bomb (pp. 4365–4367).

---

[19] Goncharov 1996a, 1996b; Chuck Hansen 1988, 2007; Rhodes 1995; Sublette 2019; Wellerstein and Geist 2017.

From the currently available sources, the detailed design of the German H-bomb is unclear. However, according to unclassified references, there are two major types of H-bomb designs.[20]

The simpler one to build is what the Soviets later called a "layer cake" (*sloika*), a spherical implosion bomb with layers of fusion fuel interspersed with layers of fission fuel. The fusion reactions contribute only a modest amount of energy, but a huge number of neutrons that enable the consumption of far more fission fuel than would otherwise be possible. The postwar Soviet nuclear program was heavily dependent upon German scientists, materials, and ideas, and the first Soviet H-bomb (Joe-4 or RDS-6, tested on 12 August 1953; see p. 1638) employed the layer cake design, with a weight of 4.5 tons, diameter of 1.5 meters, and explosive yield of 400 kilotons. Joe-4's yield could have been higher if its surrounding layer of conventional explosives had been better able to compress the layers of fission and fusion fuel [Wellerstein and Geist 2017]. If there was a wartime German design that was very similar but had 1.5 tons more of surrounding conventional explosives (total weight of 6 tons), its diameter would have been around 1.8 meters, and its explosive yield could easily have been in the 1.5-megaton range (corresponding to a six-mile blast radius).

The second major type of H-bomb is a "two-stage" design, in which the dense outer bomb casing surrounds both a fission implosion bomb (the first stage) and a neighboring mass of fusion fuel (the second stage). When the fission bomb detonates, its heat and pressure ignite fusion reactions in the adjacent fusion fuel. If the outer bomb casing is made of fission fuel (even natural uranium), high-energy neutrons from the fusion reactions can trigger extensive fission reactions in the outer bomb casing, making it effectively a third stage of the explosion. Friedwardt Winterberg, who worked very closely with Kurt Diebner after the war, published a highly distinctive ellipsoidal two-stage H-bomb design that looks rather different than standard U.S. H-bomb designs, but that is deeply steeped in earlier German hydrodynamics and physics research (p. 4373). A surviving 1944 sketch from Walther Gerlach shows an ellipsoid in conjunction with nuclear reactions involving deuterium, which seems to support the wartime origin of Winterberg's ellipsoidal H-bomb design (p. 4377).

Werner Grothmann stated that the German nuclear program was developing several different bomb types, including a hydrogen bomb. He said that the hydrogen bomb looked like a "swollen bomb" (ellipsoidal?), would have been a hundred times more powerful than a fission bomb (megatons vs. tens of kilotons), and was expected to be ready in 1946 (which suggests that it had already progressed far in its development by 1945); see pp. 3401 and 4272. Other sources expected the German hydrogen bomb to be ready even sooner, sometime in 1945, if the war had continued (pp. 4367, 4334, 4359).

In 1947, when Edward Teller was trying unsuccessfully to invent a workable design for the U.S. hydrogen bomb, he sent a highly unusual, specific, and urgent request for Siegfried Flügge to help him with a "physics... program... of interest and importance to the national security," stating that Flügge would "be of marked assistance in carrying out the aforementioned program" (p. 4996). Flügge was indeed brought to the United States, and it has never been publicly revealed what he worked on. In fact, late in the war and after the war, there was a large influx of scientists and engineers who came to the United States and/or United Kingdom and who were from or had knowledge of the German nuclear program (p. 1608). Many of those scientists appear to have been closely tied to the wartime German work on H-bombs, and may have especially aided the U.S. H-bomb development program between 1945 and 1954.

8.8.10 October 1944 Test Explosion on the Baltic Coast

A number of sources reported a test explosion on the Baltic coast in October 1944 (Section D.10).

A May 1944 U.S. Army Air Forces intelligence document listed numerous research and development sites in Germany. It correctly identified the rocket and jet propulsion work being conducted at Peenemünde and the experiments being conducted at many other highly classified locations, but noted that the "most secret research" was conducted on Rügen and Usedom islands—research even more secret than the rockets and jets (p. 4393).

In August 1944, a German prisoner of war reported that "experiments are conducted on an estate in Pomerania and it is alleged that this explosive is capable of destroying everything in a radius of several kilometers" (p. 4396).

On 20 October 1944, the U.S. physicist and intelligence analyst Philip Morrison mentioned "recent reports of Baltic explosions" that were being investigated by the Manhattan Project as possible tests of a German atomic bomb (p. 4398).

A 21 October 1944 OSS intelligence report described the October test: "The Germans have completed a weapon which is founded on the principle of the disintegration of matter (Atomzertruemmerung). Experiments have been performed which have proved conclusive[...] The radius of action is supposed to be about three kilometers" (pp. 4400–4403).

A 19 January 1945 U.S. military intelligence summary covering many areas of advanced German research included a subject heading for "ATOMIC BOMB," under which it mentioned "close surveillance of the area in which tests are alleged to have taken place" (p. 4404). The report focused largely on the most recent work being conducted on the Baltic coast, suggesting that the tests occurred in late 1944 on the Baltic coast.

In May 1945, German prisoner of war Friedrich Olmes said there had been "experiments with the atom-splitting bomb" and "practical experiments were conducted on the Baltic coast" (p. 4406).

A 19 August 1945 U.S. Army Air Forces intelligence report entitled "Investigations, Research, Developments, and Practical Use of the German Atomic Bomb" presented testimony by Rudolf Zinsser, a German pilot captured by U.S. forces, that in October 1944 he flew near the massive explosion of a new German bomb on or near the Baltic coast, describing in detail a very large mushroom cloud and severe electrical disturbances (p. 4408). After further investigation, rather than dismissing Zinsser's report, the United States decided to upgrade it from Secret to Top Secret in October 1945 (p. 4422).

In testimony in 1955, 1984, and 2005, Italian military correspondent Luigi Romersa stated that by a special arrangement between Benito Mussolini and Adolf Hitler, on 12 October 1944 he witnessed the massive explosion of a new German bomb on the Baltic coast (apparently Rügen island), had to wait in a bunker for many hours afterward for the site to become less dangerous (short radioactive half-lives?), and then had to wear a special protective suit when inspecting the leveled test site afterward (pp. 4427–4434).

Werner Grothmann stated in 2000–2002 interviews that there was a successful atomic bomb test in October 1944 (p. 4436).

In a 13 March 2005 television interview, Elisabeth Mestlin stated that she observed a massive explosion on Rügen from a neighboring island on 12 October 1944 (p. 4435).

8.8.11 Circa November 1944 Test Explosion in Poland

Multiple sources reported a test explosion in Poland in approximately November 1944 (Section D.11).

A Top Secret U.S. cable from Warsaw in March 1946 stated: “Information has been given this Embassy by a capable young engineer working in the zinc industry, that one of the best if not the only material for atomic bomb containers is cadmium” (p. 4255). This “capable young engineer” in Poland knew that atomic bomb casings included a layer of cadmium, which was true for the implosion bomb designs described by both Ilyichev and Schumann (Section 8.8.8). The Polish engineer’s knowledge suggests that German-run industry in wartime Poland was involved in developing and/or testing an atomic bomb.

Robert Jackson, chief U.S. prosecutor at the Nuremberg trials, stated on 21 June 1946 that he had received evidence that a new bomb design producing very intense heat had killed 20,000 Jewish prisoners in a specially constructed test village in Poland (p. 4458).

In August 1946, a FIAT intelligence document mentioned that there had been a number of unconfirmed reports that “about Christmas 1944, successful experiments were conducted in Pomerania with V-1 and atomic warheads, radio directed. The ensuing crater was 2 km in diameter” (p. 4460). There was also an August 1944 report of nuclear weapons development work in Pomerania (p. 4396).

In December 1946, Otto Hahn said that there had been rumors that “atom bomb tests had been carried out in Poland during the last year of the war which were supposed to have had an effect similar to the first atom bomb dropped on Hiroshima though on a considerably smaller scale” (p. 4460).

Gezo Mansfeldt, a survivor of Auschwitz, reported in December 1946 that he was frequently interrogated by Soviet officials about high-security wartime production work at Auschwitz and that he “learned of the atomic bomb tests” that were apparently related to that work (p. 4463).

A 1947 U.S. intelligence report stated that the Germans built a heavy water production plant near Auschwitz and that it was removed by the Soviets (p. 4463). Heavy water would only be useful for nuclear work, and the production of heavy water near Auschwitz suggests the presence of other nuclear work in Poland.

Another 1947 intelligence report discussed wartime nuclear weapons work at Tucheler Heide in Poland, including the production of ^{235}U and ^{239}Pu and apparently even 1–5 kg fission pits for atomic bombs (p. 4902).

In 1947, Heinrich Himmler’s physical therapist, Felix Kersten, stated that Franz Göring, a senior SS security official, had told him late in the war that a new bomb design producing several thousand degrees of heat had killed 20,000 Jewish prisoners at a test site in Poland (p. 4470).

Heinrich Himmler’s personal astrologer, Wilhelm Wulff, confirmed that Franz Göring had told him the same story about an atomic bomb test in Poland (p. 4471).

Werner Grothmann stated that there was a successful atomic bomb test in or around November 1944 (p. 4436).

8.8.12 March 1945 Test Explosions in Thuringia

A number of sources reported test explosions in Thuringia in March 1945 (Section D.12).

A 15 November 1944 letter from General Ivan Ilyichev to Joseph Stalin reported that the Germans in Thuringia were preparing under hurried but very high security conditions to test a new spherical "bomb of unusual construction" with a "large destructive power" that might be an atomic bomb (p. 4481).

A 23 March 1945 letter from General Ilyichev to Joseph Stalin reported that the Germans in Thuringia had recently conducted two very high-security test explosions of a new bomb design, described in considerable detail as a 2-ton, 1.3-meter-diameter spherical implosion device with multiple concentric layers and a ^{235}U core that created a "massive radioactive effect," incinerated or burned nearby prisoners of war, and destroyed buildings and trees within a radius of 500–600 meters (Fig. 8.32 bottom and p. 4485).

In a 30 March 1945 letter from Igor Kurchatov to General Ilyichev, Kurchatov repeated and analyzed the details reported in the 23 March 1945 letter, said it gave a "very believable description of the construction of the bomb," and requested further information (p. 4496).

21 and 29 May 1945 letters from Georgy Flerov to Igor Kurchatov reported that Flerov was currently in Dresden and en route to study the alleged German atomic test site using Geiger counters. Flerov also requested that former prisoners of war returning from Germany to the Soviet Union should be interviewed to learn if any of them knew anything about the test (p. 4503).

After all of those Soviet investigations, an October 1945 report from Marshal Georgy Zhukov to Stalin stated: "Based on the collected materials, it can be concluded that the German scientists in the field of theoretical and practical research and application of atomic energy have achieved good results up to the creation of the atomic bomb" (p. 4523).

A 1946 Russian interrogation summary reported that Robert Döpel stated that there was an atomic bomb test on a German military base before the end of the war (p. 4530).

It seems there is or at least was considerably more information about the apparent German nuclear tests in Russian government archives, including even a captured German film entitled "Film of the Launch of a V-2 and the Explosion of an Atomic Bomb" (p. 4533). At a bare minimum, there are probably documents identifying the Soviet spy who provided the information given in Ilyichev's two reports, documents reporting the suspected test site location to Flerov (which he seemed to know, but which was not in Ilyichev's two reports), documents reporting what (if anything) Flerov ultimately found, and documents describing the "collected materials" to which Zhukov referred.

21 March 1945 and 9 June 1945 U.S. aerial reconnaissance photos of the Ohrdruf Truppenübungsplatz military base appeared to show a large circular area of possible blast damage, as well as surrounding buildings and vegetation that may have been affected by blast and/or radioactive fallout, whereas a 12 August 1944 aerial reconnaissance photo did not show those features (pp. 4541–4545). There are also other potential craters of interest in the immediate vicinity.

In what appears to be a transcript of her testimony before an East German government inquiry on 16 May 1962, Cläre Werner, a wartime lookout at the Veste Wachsenburg castle near the Ohrdruf military base, reported witnessing a large nearby test explosion on 4 March and another one on 12 March 1945, as well as being informed of the historic nature of the explosions by visiting military and SS officials. She reported that she and some other local residents suffered from symptoms that sound like radiation sickness. Although there are unresolved questions about the nature and the chain of custody of the 1962 transcript, Cläre Werner confirmed the key points of her testimony in several interviews conducted between 1998 and 2003 (p. 4551).

In a transcript of his apparent testimony before the same East German government inquiry on 16 May 1962, Heinz Wachsmut reported being conscripted into a unique work assignment for the afternoon and evening of 5 March 1945 in Thuringia. He reported encountering large numbers of living, dying, and dead people suffering from what sounds like radiation sickness and burns in the aftermath of what the SS told him was a history-making test explosion. Under the close supervision of the SS, he was instructed to wear protective gear, and he burned approximately 450 bodies on woodpiles and saw a total of approximately 700 bodies being burned. (It is not clear if all of those were victims of the test explosion, or if some were victims of the daily harsh treatment of prisoners.) Afterward his protective gear and clothing were burned, he was instructed to wash himself thoroughly, and he was unable to eat for days afterward possibly due to radiation sickness. While there are again unresolved questions about the 1962 transcript, the family of Heinz Wachsmut confirmed that he had described the same events and details to them (p. 4557).

In transcripts of his testimony before East German government inquiries in 1966, Erich Rundnagel, a plumber who had worked for Kurt Diebner's nuclear research group in Thuringia during the war, reported that the scientists had told him they had two eight-kilogram atomic bombs (most likely fission pits for atomic bombs) in their safe (p. 4564).

Colonel Oscar Koch, one of George Patton's top intelligence officers, stated that a German prisoner of war described the massive explosion of a new bomb type in Thuringia in March 1945 (p. 4566).

Werner Grothmann stated in 2000–2002 interviews that there was an atomic bomb test in Thuringia on 4 March 1945 (p. 4436).

The explosive yield of the Thuringian device would have strongly depended on how much fission and fusion fuel were used. If the Thuringian device had been furnished with a $\sim$5–10 kg pit of weapons-grade fission fuel comparable to that in Gadget/Fat Man, it seems likely that it would have had a comparable yield in the $\sim$20-kiloton range. If significant fusion neutron boosting occurred from the fusion fuel at the center, the device could have fissioned far more of its fission fuel and hence achieved far larger yields—potentially up to $\sim$100 kilotons for a $\sim$10 kg pit with $\sim$50% efficiency. In fact, a number of independent contemporary sources gave the expected blast radius of the deployed device as 2–4 km (likely depending upon the amount of fuel used), corresponding to explosive yields in the range of 13–100 kilotons (p. 5168).

Ilyichev reported the blast radius of the tests was 500–600 meters. That would correspond to a yield equivalent to roughly 200–350 tons of TNT (p. 5141). To conserve weapons-grade fuel, minimize the mess made in central Germany, and avoid Allied detection, scientists would have been strongly motivated to keep the test explosion as small as possible by using just enough fuel to briefly achieve criticality during peak compression.

People at the test site would have been exposed to the prompt radiation (gamma, neutrons, and beta) released during the explosion. For a fission explosion of 200–350 tons, the lethality [10 Grays (Gy)] radius for this prompt radiation is ∼500 meters, very comparable to the blast radius [Glasstone and Dolan 1977, p. 333].

The test would also produce radioactive fallout, which would emit 80% of its total radiation within the first 24 hours and the remaining 20% more gradually over the following days, months, and years [Glasstone and Dolan 1977, pp. 390–397]. The area over which the fallout was distributed would depend on local winds and topography. Using a plausible area of ∼100 km^2 and the estimated yield of 200–350 tons, the radioactive exposure from the fallout averaged over the whole area would be ∼0.15–0.26 Gy/hr at 1 hour, or ∼1.1–2.0 Gy for the first 24 hours (p. 5146). Noticeable symptoms of radiation sickness would begin at a cumulative exposure of ∼1 Gy, very serious illness at ∼2 Gy, and fairly consistent lethality (within hours or days after exposure) at ∼10 Gy [Glasstone and Dolan 1977, pp. 575–587]. Ilyichev reported that most of the civilian population in the surrounding area had been evacuated; even those who were not may not have had enough outdoor exposure to develop symptoms. Any German teams surveying the after-effects of the explosion in nearby areas with Geiger counters would certainly have noticed the radioactive fallout.

Data from U.S. nuclear tests suggests that the fallout dosage immediately around a test site is ∼10–100 times higher than that in the much larger surrounding area that receives significant fallout, with a geometric mean value of ∼30 times higher (depending on local winds and geography) [Glasstone and Dolan 1977, pp. 419–439]. Using that mean value to multiply the area-averaged dose, ballpark values for the radiation dose right at the Thuringian test site would be ∼4.5–7.9 Gy/hr at 1 hour, or ∼34–59 Gy for the first 24 hours, lethal doses that may help to account for the lack of later witnesses.

Thus the explosion's prompt radiation at the test site, the radioactive fallout at the test site within the first 24 hours, and the radioactive fallout in nearby towns within 24 hours would easily fit Ilyichev's description that a "massive radioactive effect was observed."

After 75+ years, the radioactivity of the fallout would have dropped to $\sim 2\times10^{-9}$ of its radioactivity 1 hour after the explosion [Glasstone and Dolan 1977, p. 393], or $2.6\text{–}4.6\times10^{-6}$ Gy/yr averaged over the area and $7\text{–}14\times10^{-5}$ Gy/year at the test site. The residual radioactivity at the test site would be at least ∼10–30 times smaller than the natural background radiation ($1\text{–}2\times10^{-3}$ Gy/yr) and hence extremely difficult to detect. In fact, after 75+ years of water, wind, and human activity, the fallout could easily have become scattered over a significantly larger area than the initial area assumed here, and/or become buried to varying depths in the ground, making it even harder to detect than has been calculated here.

Therefore modern measurements of residual radioactivity cannot prove or disprove whether the March 1945 Thuringian nuclear tests (or other possible wartime German nuclear tests) occurred.

Other scientific methods (especially using mass spectrometry, particle-induced X-ray emission, neutron activation analysis, or other highly sensitive methods; looking for ^{238}U from the tamper; and comparing data at and away from the test sites to eliminate background signals), may or may not be able to detect signs of the tests.

8.8.13 Wartime/Postwar Axis Belief in the Reality of German Nuclear Weapons

Among Axis officials in positions of knowledge, there was a widespread belief in the reality of German nuclear weapons, both during and after the war (Section D.13).

One of Heinrich Himmler's closest diplomatic contacts, Grand Mufti Amin al-Husaini of Jerusalem, said Himmler had informed him in July 1943 that Germany was developing an atomic bomb (p. 4578).

Himmler's political rival, Albert Speer, confirmed that Himmler was keenly interested in developing an atomic bomb during the war (p. 4593).

Hans Ulrich Rudel, the most decorated German pilot of the war, reported that in March 1944 Hitler told him that (1) atomic bombs were at a highly advanced stage of development and (2) the bombs were intended to be delivered via V-type rockets (p. 4591).

On 5 August 1944, Hitler informed the Romanian Prime Minister Ion Antonescu that Germany had developed and would use a V-series weapon with "such a tremendous effect that all human life would be destroyed within a radius of three to four kilometers from the impact point" (p. 4594).

On 16 December 1944, Benito Mussolini stated that "thousands of German scientists are working day and night" to develop new weapons that would change the war, apparently in reference to information he received via Luigi Romersa (p. 4603).

In 16 November 1944 and 9 February 1945 letters from FBI Director J. Edgar Hoover to Franklin Roosevelt's top advisor Harry Hopkins, Hoover reported that intercepted messages from Germany to German spies in the U.S. asked the spies about "the probable reaction of the people of the United States if Germany used the explosive power obtained through the splitting of the uranium atom," high-priority targets in the United States that Germany could bomb, and methods that U.S. laboratories used to avoid criticality accidents with large quantities of enriched uranium, suggesting that Germany possessed large quantities of enriched uranium (pp. 4604–4625).

Widespread German reports from late 1944 through 1945 claimed that Germany was on the verge of deploying atomic bombs and missiles for them (p. 4627).

On 14 February 1945, Hitler told one of his doctors: "In no time at all, I'm going to start using my Victory weapon and then the war will come to a glorious end. Some time ago we solved the problem of nuclear fission, and we have developed it so far that we can exploit the energy for armaments purposes. They won't know what hit them! It's the weapon of the future. With it Germany's future is assured" (p. 4634).

Heinrich Himmler's physical therapist, Felix Kersten, and his personal astrologer, Wilhelm Wulff, independently wrote that in early March 1945, Himmler was very optimistic about the imminent success of an atomic bomb (pp. 4470, 4471).

Henry Picker, a close confidant of Hitler, wrote that before the war ended, prototype fission bombs were completed and ready, and facilities for mass-producing the bombs had been built (pp. 4635–

4639).

In 2000–2002 interviews, Werner Grothmann described how an extensive program run by Heinrich Himmler developed, tested, and debated the deployment of atomic bombs (p. 4668).

In a 1 April 1945 telegram to Allied leaders, Allen Dulles reported that Luftwaffe General Albert Kesselring mentioned deliberations among Hitler's top staff about whether to use a final secret weapon, referred to as the "desperation weapon," that would cause a "terrible blood bath" (p. 4670).

In a September 1945 interrogation, the father of an SS officer told Americans about deliberations among Hitler's top staff over an atomic bomb in April 1945 (p. 4670).

In Otto Hahn's autobiography, he wrote that he had heard from reliable sources that there were at least three completed atomic bombs at the end of the war (p. 4182). Lending additional credibility to Hahn's story, the bombs were said to be at Lüneburger Heide, which wartime Allied intelligence reports had identified as the site of what sounded like large underground uranium enrichment facilities producing fuel for spherical implosion bombs (Section 8.8.4). There were also other reports of nuclear-related work at Lüneburger Heide (pp. 4176–4181, 4406).

Former SS officer Erwin Bartmann reported very similar information from his insider knowledge of conversations among Hitler, Göring, and others—there were specific mentions of "three special bombs" and even up to nine completed bombs by the end of the war (p. 4667).

Shortly after the war, German rocket engineers Wernher von Braun and Walter Dornberger, as well as American officials who examined the German rocket program, reported that Germany planned to use its rockets to carry a "much more powerful explosive," presumably atomic bombs (p. 4681).

In the end, Germany never used nuclear weapons in combat. Franklin Roosevelt and Winston Churchill had made it clear that if Germany used anything other than conventional weapons in the war, the Allies would respond by killing millions of German civilians with crude but effective WWI-style chemical weapons (mustard agent and phosgene) or other means (pp. 2632–2651). German leaders appear to have concluded that they did not have a sufficient number of nuclear weapons and/or sufficiently reliable delivery vehicles to overcome that threat and alter the ultimate outcome of the war. Individual German political or military leaders may have also feared even greater postwar prosecutions if they used nuclear weapons, or considered it more personally beneficial to try to trade German nuclear and other technologies to the Allies than to employ them against the Allies.

8.8.14 Wartime/Postwar Allied Belief in the Reality of German Nuclear Weapons

Both during and after the war, highly placed Allied officials expressed belief in the reality of advanced German nuclear weapons programs. In fact, it appears that after the war, the four major Allied countries found and benefited from materials and expertise from the German nuclear weapons program (Section D.14). All of the relevant wartime and postwar reports with the detailed evidence remain classified or missing entirely from archives. Nonetheless, enough sources are available to prove that those reports did indeed exist, and presumably still do exist. This section gives numerous examples, although it is by no means exhaustive. See Appendix D for much more information.

In two December 1943 cables to Washington, the U.S. Military Attaché in Istanbul warned that "an engineer of the Todt organization revealed in Sofia that the Germans now possess a new type of incendiary far surpassing anything yet used in warfare. The engineer intimated that London would suffer a fate worse than that of Berlin or Hamburg in the near future." The reports added: "The Germans have a weapon in preparation which is more devastating than anything we have ever seen" (p. 4588). Germany had been mining uranium in Sofia since 1938 (Section 8.8.3).

In July 1944, Manhattan Project physicists Philip Morrison and Karl Cohen analyzed available intelligence on the German nuclear program and concluded (p. 4739):

> Recent evidence essentially confirms our earlier general statements on enemy bomb production. The reports now at hand lead us to conclude:
>
> 1. A German "Y" [enrichment] project has been underway since early 1943.
> 2. A D_2O pile is in operation, but we do not believe that this is on production level.
> 3. It is implied that a separation method is operating at a production level, for it is surely improbable that the enemy will organize a utilization group without something to use.
>
> We include a time schedule, and a technical discuss of the probable means employed.
>
> Enemy production of devices can be as high as:
>
> 1. 1 device every 3 months—on the assumption that 30 kg of material are required per device.
> 2. 1 device every month—on the assumption that 10 kg of material are required per device.
>
> In either case the first completed device could be in enemy hands now.

The *Daily Telegraph and Morning Post* reported that in August 1944, the British government had intelligence that Germany was preparing "an atomic bomb" with "an explosive radius of more than two miles," or three kilometers (p. 5011). As noted in Section 8.8.5, the Royal Air Force went to extreme lengths to bomb what appears to have been a German fission reactor and fuel reprocessing complex near Königsberg during the period 26–30 August 1944 (p. 3928).

In September 1944, the *Los Angeles Times* reported that invading U.S. troops in France had found evidence that Germany was preparing a rocket-launched bomb "with an explosive radius of three kilometers" (p. 5012).

Margaret Suckley, Franklin Roosevelt's secretary, wrote in her diary on 9 December 1944 that Roosevelt had received reliable reports that the Germans had successfully developed a bomb capable of killing everything within a mile and that the German program was "way ahead" of similar U.S. research (p. 4703).

A tantalizing December 1944 summary report from the Manhattan Project's Foreign Intelligence Unit concluded (p. 4703):

> 1. Intelligence indicates that the enemy is working in the project field. It is likely that he has undertaken one or several of the various processes for the production of bombs on a small scale and to have organized an installation equivalent to our project on final utilization. (TAB A).
>
> 2. The various methods for the production of U-233, U-235 and Pu-239 have been considered in the light of scientific development, basic materials, and industrial effort required. (TAB B). The liquid thermal diffusion process for production of U-235 on a moderate scale and the pile process using heavy water for the production of Pu-239 on a small scale appear to be the most likely possibilities; the production of U-233 on a useful scale appears to be unlikely. Activities inferred from the intelligence and other reports indicate that these processes could have come into operation during 1943. (TAB C).
>
> 3. On the basis of the above analysis it is possible for the enemy to have at least one device in his hands now, but it is improbable for him to have more than three.
>
> [Handwritten in lower right corner:] Cross referenced in Enemy Prod.[uction] of Devices—G[roves?]

Unfortunately, instead of TAB A, the collected intelligence evidence for the German nuclear weapons program, the NARA file only includes a note stating: "In the review of this file this item was removed because access to it is restricted" (p. 4707).

In March 1945, Gerard Kuiper, a highly knowledgeable investigator in the Alsos Mission, wrote a letter that contradicted what the heads of Alsos were claiming at that time (p. 4766): "One is again surprised to see quotations from U.S. senators who think that the war will be over 'within a few days'. It would be wiser to worry about the chance we still have of losing it if certain high explosives are developed in time. This possibility may, incidentally, be one reason why the Germans are not giving in."

Rather than heading toward the logical objective of Berlin to topple the German government and beat Soviet forces to the prize, U.S. troops under Generals Patton, Bradley, and Eisenhower rushed straight toward Thuringia. Justifications for this strategy have ranged from preventing Hitler from fleeing south to liberating concentration camps. However, at the very least it seems like an intriguing coincidence that Patton, Bradley, Eisenhower, and other top Allied officials were personally inspecting the Ohrdruf Truppenübungsplatz military base all together on 12 April 1945

(U.S. forces captured the base on 4 April), only a month after the possible nuclear weapons tests at that site (Section 8.8.12) [Karlsch 2005, p. 218]. Other than photos of the generals and some of the concentration camp victims, none of what must have been numerous detailed written reports about what technologies or documents the U.S. forces found at that and nearby facilities have ever been declassified and released to the public.

A 31 May 1945 cable from Eisenhower to Washington, D.C. reported: "A laboratory containing equipment and documents related to experimental work on atomic bombs and AA rockets was located near Lofer, E 7399 by Third US Army" (p. 4974). Eisenhower later told *The New York Times* how seriously he regarded the German nuclear program: "My main concern was that the Germans did not get the atomic bomb to use on us" (pp. 5033–5034).

In fact, at the end of the war, Allied investigators personally inspected many sites that conducted work related to the German nuclear weapons program, including sites in Germany (Lüneburger Heide, Hillersleben, I.G. Farben installations, numerous locations in Thuringia, etc.), Austria (St. Georgen an der Gusen, Ebensee, Redl-Zipf, Lofer, etc.), Czech territory (Pilsen, Podmokly, St. Joachimsthal/Jáchymov, etc.), and elsewhere (pp. 3670–3677, 4962–4985). Detailed reports on what they discovered and learned about the German nuclear program have never been publicly released.

In May 1945, the German submarine U-234 surrendered to the United States. It contained 560 kg of uranium oxide (possibly enriched), bomb detonators, other materials, plans, and technical experts that would have shed light on the German nuclear program. Other submarines carried additional relevant materials, documents, and personnel (Section D.14.5). Where are the many tons of documents, prototypes, and other cargo from the U-234 and the other submarines, as well as all of the reports on the German nuclear and other technology programs that the United States compiled in the process of investigating the submarines' cargoes and interrogating their passengers?

By the end of the war, SS General (and Dr. Ing.) Hans Kammler controlled and knew the details of virtually all German secret weapons research and development programs, including the nuclear weapons program. According to official histories, Kammler died in early May 1945. However, multiple documents in U.S. government archives prove that he surrendered to U.S. forces in May 1945 and was alive and being interrogated by the United States for many months (and perhaps even many years) after the war (pp. 4914–4961). The U.S. government must possess lengthy transcripts or even audio/video recordings of Kammler's interrogations. It would also possess any documents and materials that Kammler had with him when he was captured, or that he was able to direct the Americans to afterward. Kammler's interrogations and documents would almost certainly have provided the United States with considerable detail about the German nuclear program and other very advanced developments. (Albert Speer's capture and interrogation resulted in many shelves full of documents.) How can all of that Kammler material be located and declassified from U.S. government archives?

When nuclear-related censorship was relaxed somewhat after the U.S. atomic bombings of Japan in August 1945, Allied officials made a stunning admission to *Newsweek* (p. 5022): "Since the surrender of the Nazi armies, Allied officers have revealed that Germany would have been able to strike with atomic bombs by January 1945, if the invasion had not come six months before. The highest Allied officials knew that such explosives could have won the war for the Axis."

In a 25 August 1945 press release, the U.S. Office of War Information stated that "Germany's inner war secrets" included "experiments with the atomic bomb," that "Germans made significant progress in the development of an atomic bomb," and that not all "of the secrets. . . may be disclosed at this time" (p. 5023).

A 31 August 1945 U.S. report mentioned "Gerald Klein (Dr.), Dipl.-Eng., Manager of LGW. . . Worked at Peenemünde and later became group director of atomic devices in RLM. At present being used by the British. Evacuated by 'T' Force" (p. 5010). Klein was listed as the manager of "LGW," which was the Luftgerätewerk Hakenfelde A.G., part of the huge Siemens electrical company. If wartime Germany never had atomic devices or even serious plans to make them, as maintained by official histories, why did the RLM or Reichsluftfahrtministerium (Ministry of Aviation) have an entire group dedicated to atomic devices, of which Dr. Klein was the director? Where are the U.K. and U.S. reports on Klein, the organizations named, and the nuclear work?

A remarkable 14 September 1945 OSS cable hinted at far more detailed knowledge about the German nuclear weapons program than has ever been publicly released (p. 5045):

> Our work on this subject is to correlate and cooperate with specially appointed general who has charge of the whole AZUSA [German nuclear] situation and has overall responsibility. [...]
>
> On present sub feature of AZUSA about assisting locating German scientists, special general asked to have the information sent only to Calvert, London Embassy, or to Washington. [...]
>
> This now done and all AZUSA information obtained by OSS in ETO and applicable in ETO situations now to be coordinated only between you or Wisner Sibert and Calvert and advising OSS Washington of resulting decisions or information. This insures desired maximum security with fewest number persons involved. Copies of any reports to be sent OSS Washington without delay and showing action taken.
>
> This subject so tight at this time we are playing very close with special general.

Does this OSS cable show that the U.S. started to really appreciate the full extent of the wartime German nuclear program by September 1945, and took steps to limit that knowledge to the "fewest number persons"? Is that why Zinsser's report of a German atomic bomb test was upgraded from Secret to Top Secret in early October 1945 (Section 8.8.10)? Who was the "special general" mentioned in this cable—Leslie Groves or someone else?

The joint chairs of CIOS, U.S. General Thomas Jeffries Betts, Deputy G-2 of SHAEF, and U.K. Ministry of Supply chief advisor and F.R.S. Professor Reginald Patrick Linstead, wrote a 15 September 1945 final report based on specific discoveries by their CIOS investigators (p. 5030):

> Certain items have been omitted because of security considerations. . . Of particular significance were the statements, made by German experts in the rocket and controlled missile field, that much of the priority accorded their work by the German High Command was in anticipation of the use of atomic explosives. These authorities stated that KWI had repeatedly assured Hitler that an atomic explosive would be available for use within a comparatively short time. During the last months of work by the Peenemünde staff, V-weapons were designed with much smaller war-heads. Quite possibly this trend was in anticipation of the successful development of a German atomic explosive.

Thus the CIOS chairs directly contradicted the public statements of the Alsos Mission and confirmed that there was indeed a German program to develop an atomic bomb, and that it was far more than a paper design program—its hardware had passed through sufficient development, production, and testing by the end of the war that it was ready or nearly ready to be used in combat.

In September and October 1945, General George C. Marshall made several noteworthy public statements: (1) "German technological advances such as in the development of atomic explosives made it imperative that we attack before these terrible weapons could be turned against us." (2) "At the close of the German war in Europe they [U.S. factories] were just on the outer fringes of the range of fire from an enemy in Europe. Goering stated after his capture that it was a certainty the eastern American cities would have been under rocket bombardment had Germany remained undefeated for two more years. The first attacks would have started much sooner." (3) "It is not hard to predict that supersonic atomic rockets will have a profound influence on any war that ever again has to be fought" (p. 5031).

T. M. Odarenko, a longtime physicist from Bell Telephone, was one of the senior scientists involved in transferring advanced electronics and other technologies from Germany and Austria to the United States after the war. He wrote of encountering a large group of refugee nuclear scientists in Austria (pp. 4788–4785):

> Among these evacuees there is a very large group of capable scientists who worked in the field of nuclear physics and chemistry and who have been carrying this work with such facilities as they have been able to assemble. There are two (or possibly more) institutes which were directly involved before the end of the war in a secret German project called "Uranmotor" whose purpose was to split uran[ium] atoms in order to obtain a powerful source of intra-atomic energy. It is apparent that the end result of this work is a method of obtaining an explosive release of atomic energy, or atomic bomb.
>
> ——
>
> Contrary to the statements, attributed by the U.S. newspapers to the various U.S. atomic experts, that it "would take the Germans some 100 years to solve the problem of atomic disintegration on an explosive basis" (for the manufacture of bombs), the opinion of the members of the Institute themselves was that, given a supply of radium and uranium, and permitting their return to Vienna, where certain of their materials and equipments are stored, they would be able to "complete their work" in some 3 to 6 months. Some small scale experiments were claimed to be performed successfully by the Institute before the end of the war in Europe.
>
> That these claims of the Institute are not to be disregarded too readily would follow from the fact that Prof. Smyth spent considerable time with the Institute, revisited them several times, and thought it necessary to insist on the most stringent type of control over the scientific activities of the group, as well as on close individual observations. Perhaps equally significant are the indications of the substantial interest of the Russians in several members of the Institute.

"Prof. Smyth" was Charles P. Smyth, a Princeton chemistry professor and member of the Alsos Mission, who reported to Leslie Groves. Odarenko's reports on the nuclear scientists were also forwarded to Groves.[21] As a result of the reports of Odarenko and Smyth, the Austrian nuclear scientists were closely monitored and controlled for years by U.S. intelligence and military agencies. For example, the leader of the Austrian group, Georg Stetter, was kept under virtual house arrest by U.S. agents in Austria from 1945 until the 1950s, nearly destroying his career (pp. 4798–4800).

A large number of Alsos-related documents from Samuel Goudsmit's files remain classified (pp. 4772–4779). Likewise, some very important German-related files from the Manhattan Project's Foreign Intelligence Unit and the OSS remain classified and unavailable (pp. 4812–4827) [NARA RG 77, Entry UD-22A; NARA RG 226]. Even Lt. Col. George R. Eckman's "Final Report on the ALSOS Mission," written in December 1945, seems to be missing from modern archives (p. 3333). There may be countless other relevant files whose absence is not even noted in the archives.

There is evidence that Dutch intelligence provided important information about the German nuclear weapons program to the United States during and after the war (pp. 4832–4853). Samuel Goudsmit's entire folder of Dutch intelligence on the German nuclear program remains classified and unavailable.

Likewise, there is evidence that French intelligence gave important information about the German nuclear weapons program to the United States (pp. 4854–4855).

Werner Grothmann stated that the fission fuel and components of at least one German atomic bomb were found and removed from Germany by U.S. forces in 1945 (pp. 5040–5043). An archived card catalog of U.S. intelligence reports on Germany shows that there were postwar reports containing detailed information on the German atomic bomb, including a 2 January 1946 document labelled "Blueprints of Atomic Bomb," a 28 March 1946 report on "Atom Bomb Research in Germany & Influence on Developments in Soviet Russia," a 4 June 1947 report entitled "Atomic Bomb," a 25 July 1947 report on "Atomic Bomb Detonating Plans," and others. The reports themselves are still classified and unavailable to the public (pp. 5074–5075).

In private, General Leslie Groves wrote a February 1946 secret memorandum revealing (p. 4806):

> Government measures to encourage the long term exploitation of German scientists by the United States are desirable, particularly with reference to nuclear physicists and chemists who might be of some service to scientists in this country in the field of atomic energy. . . I suggest, therefore, a fifth category, defined as, those German scientists of outstanding ability in the field of nuclear physics and chemistry who, by their past reputation and present knowledge, would be of more value to the national interest of this country if they could be employed here rather than in any other country. . . However, it is extremely important that these persons be prevented from giving their services to a potential enemy of the United States.

In public, though, Groves knowingly and repeatedly made false claims that Germany's nuclear scientists had been few in number and hopelessly backward [Groves 1962].

At the "Ashcan" interrogation center after the war, Hermann Goering told his Allied interrogators that "Germany was within 90 days of producing its first atom bomb when the war ended" (p. 4894).

---

[21] NARA RG 77, Entry UD-22A, Box 174, Folder 10.10 Austria: Personnel. Shuler to Leslie R. Groves, 26 November 1945, Subject: Problem of Displaced Scientists in American Zone of Austria.

In similar postwar interrogations, Wilhelm Voss, the former director of the Skoda works, told Allied interrogators about the organization and results of the German nuclear weapons program (p. 4914).

A U.S. Department of Commerce press release praised wartime German scientific accomplishments that were more advanced than those of the United States and that were being transferred to the United States to improve its programs: “Spectacular accomplishments in uranium, nitrogen, oxygen recovery, plastics, nuclear physics and many other fields, have been uncovered in the investigation of the chemicals field alone” (p. 5066).

In July 1946, the U.S. *Army Air Forces Review* published an article stating, “it is still a matter of scientific conjecture just how many weeks—or days—it might have taken Germany to be ready with her atomic devices for the V-2s” (p. 5038).

In 1946, U.S. Army Air Forces Colonel George Woods wrote of “Germany’s Plans for the ‘A-9’ with Atomic Bomb”: “it is well known that the Germans originally had hoped to have their atomic bomb developments completed by the end of 1944.” See p. 5073.

Top Secret 1946 cables from the U.S. Joint Chiefs of Staff to General Joseph T. McNarney (the military governor of the U.S.-occupied zone of Germany and also the commander in chief of the U.S. Forces of Occupation in Europe) ordered him (pp. 5065–5066):

> Except for most cogent reasons you will not permit representatives of nations other than British Commonwealth (excluding Eire) to have access in any U.S. zone of occupation under your jurisdiction to technical information on the following subjects or to related intelligence targets:
>
> ——
>
> Applied and theoretical nuclear physics, including design and operation of devices for producing highly energetic particles, and isotope separation.

These Top Secret Orders from the highest level were written over a year after the end of the war in Europe, after the U.S. had had time to investigate wartime German programs in detail, and they specifically noted advanced nuclear-weapons-related work.

In a 17 August 1946 interrogation, Edmund Sorg described a piloted version of the V-1 cruise missile armed with an atomic bomb (p. 4896).

In discussing German rockets as weapons in an August 1947 interview, General William L. Richardson said “there is evidence to believe that the Germans intended to utilize an atomic warhead which would have made this weapon extremely deadly” (pp. 5035–5036). General Richardson would have been a highly knowledgeable and very sober source for this information. What “evidence” did he have?

In a 19 August 1947 intelligence report that is still heavily censored, Edmund Tilley discussed wartime nuclear weapons work at Tucheler Heide in Poland, including the production of ^{235}U and ^{239}Pu and apparently even 1–5 kg fission pits for atomic bombs. According to Tilley, one of the German scientists most directly responsible for that work, “Dr. Niels” (Walter Nielsch?), had already been taken to the United States for interrogation and/or work (p. 4902).

Many German and Austrian scientists who appear to have been involved in the nuclear program visited or worked in the United States and/or United Kingdom after the war. They may have provided information about wartime German work and aided the U.S./U.K. nuclear programs. Even basic files for some scientists are still not available to the public. For example, virtually the entire "Foreign Scientist Case File" (Paperclip file) of nuclear physicist Otto Haxel has been redacted in response to recent Freedom of Information Act Requests, and Wernher von Braun's Paperclip file is missing entirely. The late-wartime and postwar influx of scientists and engineers who were from or at least had knowledge of the German nuclear program included (pp. 4931–4959, 4858, 4992):

Karl-Friedrich Bonhoeffer
Wernher von Braun
Rudolf Brill
Adolf Busemann
Walter Dornberger
Rudolf Edse
Krafft Ehricke
Wilhelm Eitel
Gerhard Falck
Karl Fiebinger
Wolfgang Finkelnburg
Rudolf Fleischmann
Siegfried Flügge
Walter Glaser
Wilhelm Groth
Gottfried Guderley
Paul Harteck
Otto Haxel
Richard Herzog
Johannes Hans Jensen
Willibald Jentschke
Ulrich Jetter
Georg Joos
Hartmut Kallmann
Hans Kammler
Gerald Klein
Stanley Kronenberg
Heinz Maier-Leibnitz
Werner Maurer
Hugo Neuert
"Dr. Niels" (Walter Nielsch?)
Edgar Petersen
Heinz Schlicke
Erich Schumann
Otto Schwede
Edmund Sorg
Kurt Starke
Ernst Stuhlinger
Hans Suess
Herbert Wagner
Wilhelm Westphal
Friedwardt Winterberg
Karl Wirtz
Gernot Zippe
Etc.

This list is far from exhaustive. Furthermore, a large number of additional scientists were interrogated in Europe. The complete interrogation reports and all other files on all of these scientists and engineers should be sought and released. (Kronenberg and Winterberg came later but were educated by scientists from the wartime nuclear program and appear to have learned some of their secrets.)

From examples such as those given throughout this section and Appendix D, it is clear that there is an enormous amount of information about the wartime German nuclear weapons program that remains classified and/or hidden by various governments. Why is that the case, if the German program was as small and as primitive as government officials and historians have maintained for 75+ years? What is the true history of the German program? What is the true history of Allied knowledge about the German program, both during and after the war? Where is all of the relevant archival and physical evidence stored now?

8.8.15 Further Research That Is Needed

The very incomplete information that is currently available about the wartime German nuclear weapons program, as summarized above and in more detail in Appendix D, appears to best match the pattern of a large and advanced program, not the small and primitive program that has generally been depicted for the last 75+ years (Section D.15). Some readers may object to this claim, but historians should actively search for additional information that could help to confirm or refute this picture:

- Any relevant records in U.S., U.K., French, Russian, or other national archives should be located, declassified, and released to the public. Even from the currently available evidence, it is abundantly clear than highly relevant documents (wartime intelligence on German nuclear tests and progress; postwar interrogations of Hans Kammler, German and Austrian nuclear scientists, and other key players; reports on postwar investigations of nuclear-related sites and submarines; etc.) remain classified and unavailable to the public. The war ended 75+ years ago, and government censorship of all those historical documents must finally end.

- Any relevant information in personal collections (war diaries, preserved documents, photographs, etc.) should be located, authenticated, and analyzed with the other available data.

- Thorough scientific analyses of suspected test sites should be conducted (especially using mass spectrometry, particle-induced X-ray emission, neutron activation analysis, or other highly sensitive methods; looking for ^{238}U from the tamper; and comparing data at and away from the test sites to eliminate background signals), although after 75+ years of radioactive decay and weathering, even the most diligent testing might be inconclusive.

- Extensive and meticulous industrial archaeological digs should be conducted at sites suspected to have been involved in developing or storing nuclear materials or nuclear weapons. Even if much of the material at those sites had been removed by German or Allied forces, any remaining evidence could provide conclusive proof about the nature and extent of the wartime nuclear program.

Until those searches have been thoroughly conducted, historians and scientists should cease making authoritative-sounding declarations that the nuclear program was small and unsuccessful, since there is already a great deal of evidence to the contrary.

If the German nuclear weapons program was indeed successful, one can understand why the major countries involved would have wanted to conceal that fact at the end of World War II and the beginning of the Cold War. Individual Germans with knowledge of the program would not want to appear guilty of additional acts for which they might be punished after the war. Key German players may have been rewarded for offering the fruits of the nuclear program to Allied nations and remaining silent. For purposes of internal morale and external public image, Allied countries would prefer to claim that such technological accomplishments were really their own, and in any case would be highly motivated to try to protect any new weapons technologies from rival Allied nations in the incipient Cold War.

Likewise, if the German nuclear weapons program was successful, one can also understand why the major countries involved might desire to preserve that secret even 75+ years later. The German and

Austrian governments might not want yet another Third Reich offense from their past for which they would need to apologize. Former Allied countries might not want to admit that their wartime and postwar technological prowess was not as great as they had boasted for so many decades, or that that of their vanquished enemy was greater than they had claimed for so long. In any event, routine security classification rules would prevent the release of archival documents with useful details about nuclear weapons designs and production methods, no matter what their age, history, and country of origin might have been (even though far more dangerous, detailed, and up-to-date information is now readily available to everyone on the internet).

Yet if the German nuclear weapons program truly was more successful than the governments have previously admitted, on the whole it would seem far more beneficial for all countries to finally acknowledge that fact than to continue to deny it:

1. As with "truth and reconciliation commissions" in other countries, Germany and Austria could finally acknowledge and address the full extent of the Third Reich's actions, their current citizens (who were too young to have been involved in any of those events) could have a detailed understanding of those actions and history, and these countries could move forward with that chapter fully closed, rather than still having to hide or fear further revelations in the indefinite future.

2. Carefully inspecting and cleaning up any sites involved in producing or storing nuclear materials would prevent contamination of local drinking water, farms, and homes with radioactive isotopes, heavy metals, solvents, or other toxic chemicals.

3. Elucidating all the concentration camp prisoners who died in the preparation, production, and testing of nuclear weapons would finally bring justice to what may be many thousands of currently forgotten victims of the war.

4. The media-consuming public in former Allied countries seems fascinated with and proud of their countries' roles in World War II, so they should be extremely interested in new details about that war, and should in fact find it exciting to learn that their victory was even more hard-won and more consequential than previously known (somewhat similar to how sports fans are more excited by especially close or high-stakes wins).

5. Everyone would gain a much better understanding of the strategic decisions made by all countries during and after the war, making more sense of events and actions that have previously not been as well explained in the history books.

6. All nations would benefit tremendously by learning exactly how revolutionary technologies have been created in the past, so that they could better create and enjoy the benefits of new revolutionary technologies in the future.

For much more information on the German nuclear weapons program, see Appendix D.

For information on wartime German programs to develop intercontinental jets, rockets, and other delivery vehicles for nuclear weapons, see Appendix E.

8.9 Nuclear Engineering in the Soviet Union

German-trained scientists and engineers, as well as German-produced designs, materials, and equipment, made enormous contributions to the postwar Soviet nuclear program.[22]

The Soviet nuclear program employed (at least) many hundreds of German-speaking scientists and engineers. Just the Soviet nuclear institute run by Manfred von Ardenne was staffed with almost 300 Germans [Oleynikov 2000]. At least several hundred more worked at other nuclear institutes and facilities in the Soviet Union.[23] Including German-speaking scientists and engineers in industries that directly supported the nuclear program (geology, chemistry, materials science, electronics, aerospace, etc.), the total number of German-speaking specialists who contributed to the program was likely in the thousands. For examples of some German-speaking scientists who aided the Soviet nuclear program, see Figs. 8.52–8.55. Some of the major contributions included:

- Klaus Fuchs, a German physicist who worked in the U.S./U.K. nuclear program for many years, gave the Soviet Union detailed plans of U.S. nuclear bombs and production systems (which had been designed and developed with the critical contributions of a large number of German-speaking and German-trained scientists, as discussed in Section 8.7).

- Erich Purucker (German, 1893–1957), Hans Kammler's chief assistant in running the wartime German nuclear program, was captured by Soviet troops in May 1945 along with a car full of German nuclear weapons plans, and held in the Soviet Union for the rest of his life. See p. 4914 for more details.

- E. Baroni (German, ??-??), Henry Ortmann (German, 1908–1988), Nikolaus Riehl (German, 1901–1990), Herbert Schmitz (German, ??–??), Herbert Thieme (German, 1902–??), Günther Wirths (German, 1911–2005), and many other German and Austrian scientists processed uranium ore to uranium oxide, uranium metal, and uranium hexafluoride. Joseph Stalin personally awarded Riehl the title "Hero of the Socialist Labor" and gave him a first class Stalin Prize; he gave Thieme and Wirths second class Stalin Prizes.

- Heinz Barwich (German, 1911–1966), Fritz Bernhard (German, 1913–??), Gustav Hertz (German, 1887–1975), Hans Gerhard Krüger (German, 1912–??), Justus Mühlenpfordt (German, 1911–2000), Reinhold Reichmann (German, ??–??), Werner Schütze (German, ??–??), Peter Thiessen (German, 1899–1990), and many other German and Austrian scientists produced gaseous diffusion systems to enrich uranium-235, apparently based on wartime German gaseous diffusion technology. Joseph Stalin gave Thiessen a first class Stalin Prize, and Barwich, Hertz, Reichmann, and Schütze second class Stalin Prizes.

[23] Rainer Karlsch, unpublished Soviet archival list of personnel files.

- Fritz Lange (German, 1899–1987), Rudolf Scheffel (German, 19??–19??), Max Steenbeck (German, 1904–1981), Eberhard Steudel (German, 1906–19??), Gernot Zippe (Austrian, 1917–2008), and many other German and Austrian scientists produced gas centrifuges to enrich uranium-235, apparently based on wartime German gas centrifuge technology.

- Manfred von Ardenne (German, 1907–1997), Werner Schütze, Max Steenbeck, and many other German and Austrian scientists produced electromagnetic separators to enrich uranium-235, apparently based on wartime German electromagnetic separation technology.

- Hans-Joachim Born (German, 1909–1987), Alexander Catsch (German, 1913–1976), Nikolai Timoféeff-Ressovsky (Russian but German educated, 1900–1981), Karl Günter Zimmer (German, 1911–1988), and other German and Austrian scientists elucidated the biological effects of radiation, as well as methods to protect against it, based on their earlier research in Germany.

- Victor Karl Bayerl, Ludwig Bewilogua (German, 1906–1983), Werner Czulius (Austrian, 1914–2007), Karl-Hermann Geib (German, 1908–1949), Paul Herold (German, ??–1951), Walter Herrmann (German, 1910–1987), Paul Heylandt (German, 1884–1947), Hans Gerhard Krüger, Hans-Jürgen von Oertzen (German, 1907–??), Heinz Pose (German, 1905–1975), K. Renker (German, ??–??), Ernst Rexer (German, 1902–1983), Gustav Richter (German, 1911–1999), Karl-Heinz Riewe (German, 1907–??), Adrian Rosen (German, ??–??), Herbert Schmitz, Max Volmer (German, 1885–1965), Carl Friedrich Weiss (German, 1901–1981), Hans Westmeyer (German, 1910–??), and many other German and Austrian scientists developed fission reactors for breeding plutonium-239 from natural uranium-238, based on wartime German technology.

- Manfred von Ardenne, Gustav Hertz, Carl Kober (German, 1913–??), Josef Schintlemeister (Austrian, 1908–1971), Werner Schütze, and other German and Austrian scientists developed methods of producing and using lithium and tritium in H-bombs, apparently based on wartime German and Austrian work. (See p. 4347 as well as the rest of Section D.9.) Von Ardenne was awarded two first class Stalin Prizes for his multiple contributions in the Soviet Union, including the purification of lithium-6 for H-bombs.

Even Pavel Oleynikov, a former group leader of the Chelyabinsk-70 nuclear weapons complex in Russia, admitted that German scientists, technologies, ideas, and materials had had a profound effect on the development of nuclear weapons in the Soviet Union [Oleynikov 2000]:

> It is hard to fully explore the German contributions to the Soviet atomic project without performing a detailed examination of the whole Soviet atom bomb effort. What is clear from the available evidence is that German involvement had several very important implications for the Soviet Union and the world:
>
> - German resources jump-started the Soviet program and saved it up to five years of time. If not for this time, the USSR could hardly have been as aggressive as it was in seeking global dominance. Very likely, the USSR could not have wielded its influence in Asia, and the whole course of regional history (e.g., the Korean War) would have been different. [...]

> - Participation of German scientists in the development of new uranium enrichment methods revolutionized the whole uranium fuel industry. The work of Max Steenbeck and Gernot Zippe shaped the European and Japanese enrichment plants, and was used by several later proliferators (e.g., Pakistan and Iraq) as well.
>
> In sum, although the Soviets would have eventually developed nuclear weapons on their own, they benefited considerably from German technology, expertise, and raw materials. The German contributions undoubtedly accelerated the program by several years and enhanced the Soviets' stature on the world stage. An accurate and complete history of the Soviet bomb program must acknowledge the importance of the Germans' contributions.

At a minimum, the contributions of all of those German-trained scientists and all of the nuclear-related materials taken from Germany appear to have accelerated Soviet development of fission and fusion bombs by many years (Figs. 8.56–8.57). Although some historians have studied this area, much more detailed investigations are needed, especially if unrestricted access to former Soviet archives becomes available.

Chapter 9

Creators and Creations in Aerospace Engineering

Dieses merkt Euch, Ihr stolzen Männer der Tat. Ihr seid nichts als unbewußte Handlanger der Gedankenmänner, die oft in demütigster Stille Euch all Euer Tun aufs Bestimmteste vorgezeichnet haben.

Mark this well, you proud men of action. You are nothing but the unconscious hands of the men of thought, who have often, in the most humble silence, directed all your actions in advance.

Heinrich Heine. 1834. *Zur Geschichte der Religion und Philosophie in Deutschland* [*History of Religion and Philosophy in Germany*] Book III, paragraph 3.

This chapter gives an overview of some innovations in aerospace engineering that have played major roles in the modern world and that were invented or discovered by scientists and engineers who were trained in the predominantly German-speaking central European research world in the nineteenth and early twentieth centuries.[1]

---

[1] In addition to specific references that are cited in different areas throughout this chapter, this chapter makes use of general biographical and project information from: ACLS 2000; Albrecht et al. 1992; Ash and Söllner 1996; Bar-Zohar 1967; Bower 1987; Bunch and Hellemans 2004; Challoner 2009; Cornwell 2003; Crim 2018; EB 1911, 2010; Gillispie 1970–1990; Gimbel 1990a; Glatt 1994; Hall 2019a; István Hargittai 2006, 2011; Linda Hunt 1991; Impey et al. 2008; Jacobsen 2014; Koertge 2007; Kurowski 1982; Lasby 1971; Lusar 1956, 1971; Medawar and Pyke 2000; Mick 2000; Murray 2003; Nachmansohn 1979; NDB 1953–2020; Neufeld 2012; Nouzille and Huwart 1999; O'Reagan 2014, 2019; Porter 1994; Charles Walker 1946; Peter Watson 2010; Weitensfelder 2009.

For general overviews of large portions of the history of aerospace engineering in the German-speaking world, see: Benecke and Quick 1957; von Braun et al. 1985; Coats and Carbonel 2002; Freeman 1993, 2008; Griehl 1990, 2003, 2004, 2005, 2015; Hirschel et al. 2004; Kay 2002; Lommel 2000, 2002, 2005; Jürgen Michels 1997; Myhra 1998a, 1998b, 2000a, 2000b, 2001, 2002, 2003; Michael Neufeld 1995, 2002, 2003, 2004, 2007, 2012; Ordway and Sharpe 1979; Samuel 2004, 2010; Smith and Creek 1982, 1992, 2001; Smith and Kay 2002; Stüwe 1999, 2014, 2015; Trischler 1992a, 1992b; Trischler and Schrogl 2007; Frank Winter 1983, 1990.

Creators from the German-speaking world made major contributions to:

9.1. Lighter-than-air craft

9.2. Aerodynamics and aircraft design

9.3. Jet engines and jet aircraft

9.4. Parachutes and ejection seats

9.5. Helicopters

9.6. Small missiles and smart bombs

9.7. Large liquid propellant rockets

9.8. Submarine-launched and solid propellant rockets

9.9. Rocket planes and space planes

9.10. Space exploration

9.1 Lighter-Than-Air Craft

Lighter-than-air craft use low-density gas (hot air, hydrogen, or helium) rather than powered engines to stay aloft. The simplest lighter-than-air craft is a balloon, and the French brothers Joseph-Michel and Jacques-Étienne Montgolfier are believed to have conducted the first piloted hot-air balloon flights in 1783. By the late nineteenth century, balloons were a well developed and widely utilized technology. However, their greatest weakness was that they were at the mercy of the prevailing winds and nearly impossible to guide.

I have deliberately left a blank space where images of some creators or creations should go. Those are people or projects that I felt were important enough that they should definitely be shown in this book, yet I have not yet been able to locate a suitable image that I have permission to use, despite my searches in Europe and in the United States. If readers have any relevant images and could send them to me, I would be very grateful and will include them in future editions of this book. Even where a suitable photo cannot be located, I believe that leaving a blank space pays tribute both to the scientific importance of that creator or creation and to how that historical fact has been very nearly forgotten.

German-speaking creators played leading roles in transforming spherical, unpowered balloons that could not be guided into long, aerodynamic, internal-combustion-engine-powered, propeller-driven airships that could follow any desired course, even between continents [Danelek and Davis 2011; Hirschel et al. 2004].[2]

Those German-speaking creators developed:

1. Non-rigid airships, in which the giant envelope holding the low-density gas is simply an inflatable sack like a balloon.

2. Semi-rigid airships, in which the envelope is partially supported by a skeleton of light-weight materials such as aluminum or wood to hold its shape.

3. Rigid airships, in which the envelope is fully supported by a stiff skin of light-weight materials such as aluminum or wood to hold its shape regardless of gas pressure.

Some of the earliest German-speaking pioneers of powered airships are shown in Fig. 9.1:

- Paul Haenlein (German, 1835–1905) built and tested a small semi-rigid airship with an internal combustion engine in 1872.

- Hermann Ganswindt (German, 1856–1934) was a very creative inventor who experimented with early forms of both lighter-than-air and heavier-than air flying machines; see pp. 1798 and 1953.

- Georg Baumgarten (German, 1837–1884) and Friedrich Wölfert (German, 1850–1897) built and tested a series of non-rigid airships 1880–1897. They probably would have had a much greater ultimate impact, but Baumgarten died along the way, and Wölfert died in the crash of the final airship.

David Schwarz (Austro-Hungarian/Croatian, 1850–1897), his wife Melania Kaufmann Schwarz (Austro-Hungarian?, 1858–19??), and Carl Berg (German, 1851–1906) developed the first rigid airship, the Schwarz II, which first flew in Berlin in 1897; see Fig. 9.2. David Schwarz died of heart failure only months before the first flight of his invention, but Melania Schwarz and Carl Berg finished the project. Berg, who had developed and supplied aluminum alloys for that project, continued to do so for other airships.

After Count Ferdinand von Zeppelin (German, 1838–1917) retired from the German army in 1890, he wanted to realize the full potential of airships, which had so far only been small, unreliable prototypes. Along with Heinrich Müller-Breslau (German, 1851–1925), Theodor Kober (German, 1865–1930), Carl Berg, and other engineers, he developed a series of increasingly sophisticated rigid airships or Zeppelins, beginning with the LZ 1, which first flew in 1900, as shown in Fig. 9.3. Examples of later Zeppelins depicted in Fig. 9.4 included the LZ 3 (first flight 1906, and here shown over Berlin in 1909), LZ 72 (first flight 1916), and LZ 129 *Hindenburg* (first flight in 1936 and destroyed in 1937).

---

[2] There were some French engineers who tested early airships that used other power sources which were too weak and/or short-lived to be practical: Henri Giffard (1825–1882) with his steam-powered airship (1852), and Arthur Krebs (1850–1935) and Charles Renard (1847–1905) with their battery-powered airship (1884).

Encyclopedia Britannica explained the progression of Zeppelin's team from initial prototypes to a working fleet [EB 2010]:

> He retired in 1890 and devoted the rest of his life to the creation of the rigid airship for which he is known.
>
> Zeppelin struggled for 10 years to produce his lighter-than-air craft. The initial flight (July 2, 1900) of the LZ-1 from a floating hangar on Lake Constance, near Friedrichshafen, Ger., was not entirely successful, but it had the effect of promoting the airship to the degree that public subscriptions and donations thereafter funded the count's work. The German government was quick to perceive the advantage of airships over the as yet poorly developed airplanes, and when Zeppelin achieved 24-hour flight in 1906, he received commissions for an entire fleet. More than 100 zeppelins were used for military operations in World War I. A passenger service known as Delag (Deutsche-Luftschiffahrts AG) was established in 1910, but Zeppelin died before attaining his goal of transcontinental service.

In addition to his work on airships, Heinrich Müller-Breslau made many other important contributions to structural engineering and the theory of stress and strain.

As shown in Fig. 9.5, Johann Schütte (German, 1873–1940) and Karl Lanz (German, 1873–1921) rivaled Zeppelin with their own series of increasingly sophisticated airships that tended to use wood instead of aluminum.

Hans Groß (German, 1860–1924) and Nikolaus Basenach (German, 1875–1951) developed a series of semi-rigid airships, such as the Groß-Basenach M I airship (first flight in 1908 and enlarged in 1913, Fig. 9.6).

August von Parseval (German, 1861–1942), August Riedinger (German, 1845–1919), and Rudolf von Sigsfeld (German, 1861–1902) developed increasingly sophisticated non-rigid airships, such as the Parseval Versuchsluftschiff (1907) and PL19 airship (1914), as shown in Fig. 9.7.

Auguste Piccard (Swiss, 1884–1962) and Paul Kipfer (Swiss, 1905–1980) created and tested high-altitude balloons and used them to make measurements of the upper atmosphere and of cosmic rays. Jean Piccard (Swiss, 1884–1963), Auguste Piccard's twin brother, also invented and tested many high-altitude balloon designs. See Fig. 9.8.

9.2 Aerodynamics and Aircraft Design

German-speaking creators played such a dominant role for nearly a century in the development of aerodynamics and aerodynamics-guided aircraft designs that only a few examples of those creators and their creations can be mentioned here, representing the following areas:[3]

9.2.1. First aircraft

9.2.2. Aerodynamics experiments and theory

9.2.3. Specialized aircraft

9.2.4. High-speed aircraft design

For closely related contributions by German-speaking creators to jet engines and jet aircraft, see Section 9.3.

9.2.1 First Aircraft

George Cayley (English, 1773–1857) built the first known successful piloted glider in 1853. Although Cayley does not fall within the scope of this book, he deserves to be studied and remembered far more in his own right [Dee 2007]. Cayley's demonstration caught the attention of people around the world, and especially engineers in rapidly industrializing Germany.

As shown in Fig. 9.9, Otto Lilienthal (German, 1848–1896) developed and flew very innovative gliders with improved lift and maneuverability. He would likely have gone on to make the first powered airplane flights if he had not died from a glider crash in 1896 [Harsch et al. 2008; Heinzerling and Trischler 1991]. Oxford University's *Biographical Dictionary of Scientists* described Lilienthal's importance in the history of flight [Porter 1994, p. 432]:

> Lilienthal [...] was a German engineer whose experiments with gliders helped to found the science of aeronautics. But for his premature death in a flying accident, he might well have beaten the Wright brothers to the achievement of powered flight. [...]
>
> Lilienthal flew the first of his famous series of gliders in 1891, and continued, until his final fatal glide in 1896, to hold to his fundamental conviction that the key to eventual powered flight was in glider-flying, in which pilots could master the elements of control and design. [...] The step to powered flight was a straightforward progression from advanced gliding. The Wrights' breakthrough was a simple extension of their own work with gliders, which in turn was greatly helped by Lilienthal's many glides and careful observations. Among other things, he had demonstrated the superiority of cambered wings over flat wings—the principle of the aerofoil.

Gustav Weisskopf (German, 1874–1927) very closely studied the work of Lilienthal, then moved to the United States, where he became known as Gustave Whitehead. Weisskopf settled in Connecticut, where he built a long series of powered aircraft prototypes. There is considerable evidence that

---

[3] E.g., see: Amtmann 1988; Anderson 1997; Beauvais 2002; Bohr 2013; Brinchman 2015; Budrass 1998; Butler 1994, 2007; Chant 1999; Danelek and Davis 2011; Eckert 2017; Gorn 1992; Griehl 1990, 2004, 2005, 2015; Hanle 1982; Heinzerling and Trischler 1991; Herwig and Rode 2000, 2003; Hirschel et al. 2004; von Kármán 1945, 1967; Krehl 2009; Lommel 2000, 2002; Hans-Ulrich Meier 2010; Myhra 1998a, 1998b, 2000a, 2000b; Rotta 1990; Samuel 2004, 2010; Schick and Meyer 1997; Smith and Creek 1982, 1992, 2001; Smith and Kay 2002; Stüwe 1999, 2014, 2015; Trischler 1992a, 1992b; Trischler and Schrogl 2007; Vajda and Dancey 1998; Wegener 1996; CIOS XXVIII-47.

Weisskopf successfully conducted the first piloted flights of a powered airplane in 1901, covering a distance of approximately half a mile on the first flight, and several miles in subsequent flights:

1. Multiple witnesses reported that Weisskopf's airplane flew.
2. Many contemporaneous newspaper articles reported that his airplane flew.
3. Many contemporaneous newspaper articles reported that there were photographs showing Weisskopf's airplane flying (although the photographs cannot be located now).
4. Modern replicas of his aircraft successfully flew in tests made in the 1980s and 1990s.

If those claims are true, Weisskopf's first piloted, powered flight occurred over two years before the Wright Brothers' far more famous first flight, was much longer than the Wright Brothers' first flight, and was subsequently improved and repeated several times.

The details of Weisskopf's claims and the details of the evidence are still hotly debated.[4] Nonetheless, they seem to deserve far more open-minded and serious historical attention than they have generally received.

Surprisingly, the major relevant museums and scholars in the United States are legally forbidden from just that sort of open-minded and serious evaluation of the historical evidence. In 1948, the estate of the Wright family donated the Wright brothers' 1903 airplane to the Smithsonian Institution and the United States under extraordinary conditions that were agreed to in a legally binding contract (Figs. 9.11–9.12). That contract stipulated that the Wright airplane must be displayed immediately inside the museum entrance—accompanied by specific language stating that it was the first airplane—and that the museum and any affiliated organizations were legally forbidden to question whether there might have been any earlier successful airplanes:

> [...] Neither the Smithsonian Institution or its successors nor any museum or other agency, bureau or facilities, administered for the United States of America by the Smithsonian Institution or its successors, shall publish or permit to be displayed a statement or label in connection with or in respect of any aircraft model or design of earlier date than the Wright Aeroplane of 1903, claiming in effect that such aircraft was capable of carrying a man under its own power in controlled flight.
>
> 3. The title and right of possession to be transferred by the Vendors hereunder shall remain vested in the United States of America only so long as there shall be no deviation by the Vendee from the requirements of the foregoing paragraph[...]

Thus the major science history museums, curators, historians, and scholars of the United States are legally obligated to ignore any evidence that Gustav Weisskopf or anyone else may have been successful before the Wright brothers, or else they will lose the world-famous exhibit that hangs in the very center of the National Air and Space Museum in Washington, D.C. This 1948 contract was the culmination of many decades of action by the Wright family and their powerful allies against the relatively undefended and impoverished legacy of Gustav Weisskopf, which might also explain why some of the documentary evidence for Weisskopf's flights (such as numerous photographs that were described in contemporaneous accounts) disappeared over the years.

AGREEMENT

THIS AGREEMENT made by and between HAROLD S. MILLER and HAROLD W. STEEPER as Executors of the Last Will and Testament of Orville Wright, deceased, hereinafter called the Vendors, Parties of the First Part, and THE UNITED STATES OF AMERICA, hereinafter called the Vendee, Party of the Second Part, WITNESSETH:

WHEREAS there is included in the residuary estate of Orville Wright the Wright Aeroplane of 1903, invented and built by Wilbur and Orville Wright and flown by them at Kitty Hawk, North Carolina on December 17, 1903, and

WHEREAS it is in the public interest that said plane be preserved for all time and made available as a public exhibit in an appropriate place and under proper auspices, and

WHEREAS the Probate Court of Montgomery County, Ohio, having jurisdiction over the administration of said estate, after full hearing in a proceeding to which all persons and institutions having any interest under the will of Orville Wright were parties and had submitted themselves to the jurisdiction of the Court, has officially found that the known wishes of Orville Wright will be carried out and the highest and best interest of the estate will be served by recognizing the public interest and has accordingly authorized and directed the Vendors to enter into this Agreement,

NOW, THEREFORE, THIS AGREEMENT WITNESSETH:

1. For the consideration hereinafter set forth the Vendors agree to sell and do hereby sell to the United States of America, and agree to deliver to the United States National Museum, Washington, D.C., within the current fiscal year ending June 30, 1949, and subject to the terms of this Agreement, the original Wright Aeroplane of 1903.

2. In consideration thereof the Vendee agrees to pay to the Vendors the sum of One ($1.00) Dollar in cash and to comply with the following requirements:

(a) Said aeroplane is to be displayed as a public museum exhibit in the Metropolitan Area of the United States National Capital only, and except as hereinafter provided in paragraph (b) is to be housed directly facing the Main Entrance in the fore part of the North Half of the Arts and Industries Building of the United States National Museum. It shall never be removed from such public exhibition except as may be required temporarily for maintenance or protection.

(b) If the proper authorities of the Smithsonian Institution or its successors (acting for the United States of America) at any time in the future desire to remove said aeroplane to any other building in the Metropolitan Area of the national capital, such removal shall be permitted on the following conditions:

1. That the substituted building shall have equal or better facilities for the protection, maintenance and exhibition of the aeroplane.
2. That the Wright Aeroplane of 1903 be given a place of special honor and not intermingled with other aeroplanes of later design.
3. That such building be not a military museum but be devoted to memorializing the development of aviation.

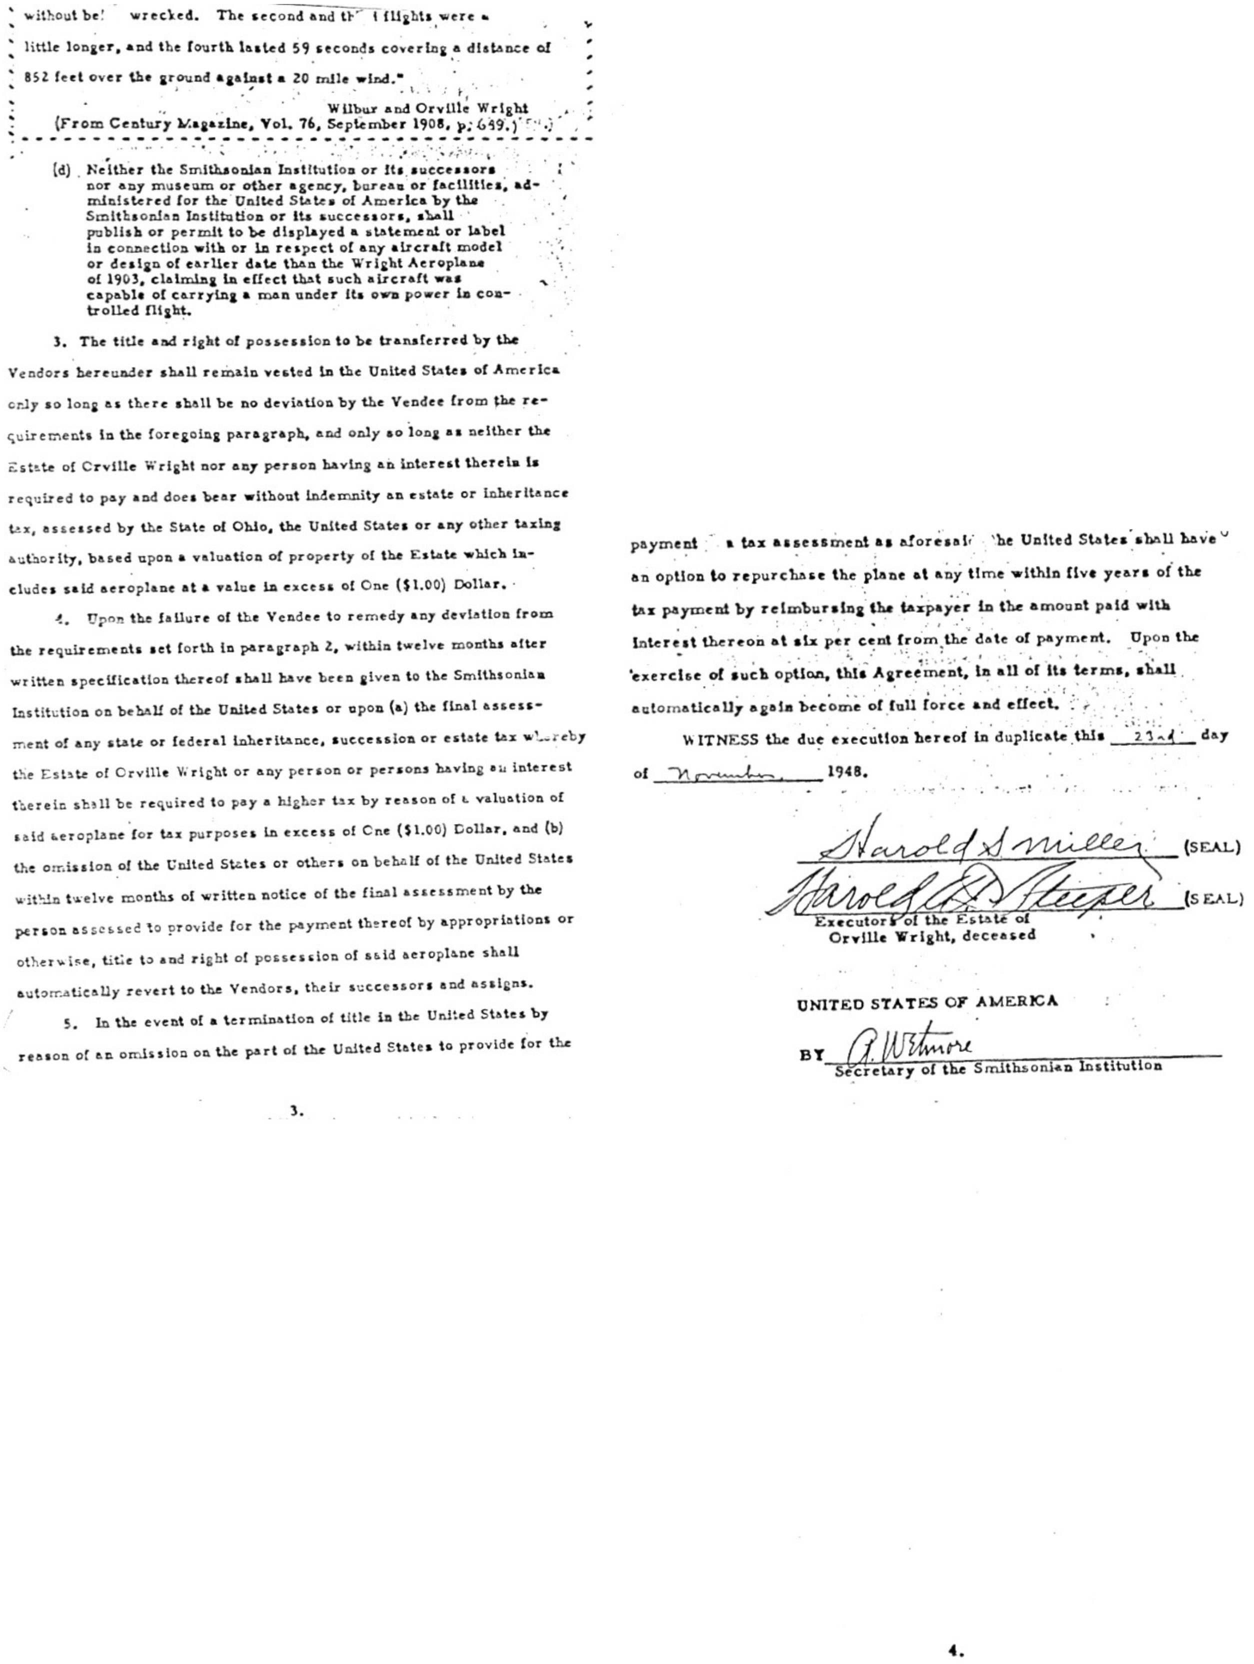
(c) There shall at all times be prominently displayed with said aeroplane a label in the following form and language:

The Original Wright Brothers' Aeroplane
The World's First Power-Driven Heavier-than-Air Machine
in Which Man Made Free, Controlled, and
Sustained Flight
Invented and Built by Wilbur and Orville Wright
Flown by Them at Kitty Hawk, North Carolina
December 17, 1903
By Original Scientific Research the Wright Brothers Discovered
the Principles of Human Flight
As Inventors, Builders and Flyers They Further Developed the Aeroplane
Taught Man to Fly and Opened the Era of Aviation
Deposited by the Estate of Orville Wright.

"The first flight lasted only twelve seconds, a flight very modest compared with that of birds, but it was nevertheless the first in the history of the world in which a machine carrying a man had raised itself by its own power into the air in free flight, had sailed forward on a level course without reduction of speed, and had finally landed

2.

Figure 9.11: As a condition for possessing the Wright Brothers' 1903 airplane, the U.S. Smithsonian Institution and related organizations are legally forbidden from questioning whether Gustav Weisskopf/Gustave Whitehead or others may have succeeded before the Wrights [see http://gustavewhitehead.info/smithsonian-conspiracy-to-deny-whitehead-flew-first/ for this and additional related documents and information].



without be! wrecked. The second and th i flights were a little longer, and the fourth lasted 59 seconds covering a distance of 852 feet over the ground against a 20 mile wind."

Wilbur and Orville Wright
(From Century Magazine, Vol. 76, September 1908, p. 649.)

(d) Neither the Smithsonian Institution or its successors nor any museum or other agency, bureau or facilities, administered for the United States of America by the Smithsonian Institution or its successors, shall publish or permit to be displayed a statement or label in connection with or in respect of any aircraft model or design of earlier date than the Wright Aeroplane of 1903, claiming in effect that such aircraft was capable of carrying a man under its own power in controlled flight.

3. The title and right of possession to be transferred by the Vendors hereunder shall remain vested in the United States of America only so long as there shall be no deviation by the Vendee from the requirements in the foregoing paragraph, and only so long as neither the Estate of Orville Wright nor any person having an interest therein is required to pay and does bear without indemnity an estate or inheritance tax, assessed by the State of Ohio, the United States or any other taxing authority, based upon a valuation of property of the Estate which includes said aeroplane at a value in excess of One ($1.00) Dollar.

4. Upon the failure of the Vendee to remedy any deviation from the requirements set forth in paragraph 2, within twelve months after written specification thereof shall have been given to the Smithsonian Institution on behalf of the United States or upon (a) the final assessment of any state or federal inheritance, succession or estate tax whereby the Estate of Orville Wright or any person or persons having an interest therein shall be required to pay a higher tax by reason of a valuation of said aeroplane for tax purposes in excess of One ($1.00) Dollar, and (b) the omission of the United States or others on behalf of the United States within twelve months of written notice of the final assessment by the person assessed to provide for the payment thereof by appropriations or otherwise, title to and right of possession of said aeroplane shall automatically revert to the Vendors, their successors and assigns.

5. In the event of a termination of title in the United States by reason of an omission on the part of the United States to provide for the

3.

payment a tax assessment as aforesai he United States shall have an option to repurchase the plane at any time within five years of the tax payment by reimbursing the taxpayer in the amount paid with interest thereon at six per cent from the date of payment. Upon the exercise of such option, this Agreement, in all of its terms, shall automatically again become of full force and effect.

WITNESS the due execution hereof in duplicate this 23rd day of November 1948.

9.2.2 Aerodynamics Experiments and Theory

Two brilliant Swiss mathematicians laid the foundations for the mathematical theory of fluid mechanics and aerodynamics in the 1700s:

- Daniel Bernoulli (Swiss, 1700–1782) developed the Bernoulli equation for incompressible, inviscid fluid flow, and published it in 1738 (Fig. 9.13). The Bernoulli equation is useful for designing barometers, finding the aerodynamic lift of aircraft wings, calculating the aerodynamic drag on vehicles and parachutes, explaining meteorological phenomena, and analyzing other applications. Bernoulli also made important contributions to mathematics and to the theory of flexible beams.

- Leonhard Euler (Swiss, 1707–1783) developed the more general Euler equations for fluid flow, which greatly extend the Bernoulli equation for many other conditions and applications, and published them in 1757 (Fig. 9.14). He also made extensive contributions to calculus, complex number theory, topology and graph theory, mechanical stress and strain calculations, astronomy, optics, logic, and other topics [Calinger 2015; Richeson 2008].

As illustrated in Fig. 9.15, Ernst Mach (Austrian, 1838–1916), his son Ludwig Mach (Austrian, 1868–1951), and Peter Salcher (Austrian, 1848–1928) conducted the first experiments to visualize shock waves around a bullet traveling faster than the speed of sound through air. The speed of an object compared to the speed of sound is now called the Mach number.

Ernst Mach excelled both at experimental technique—as demonstrated by his ability to capture detailed images of a bullet in flight without any electronic timing equipment—and at finding the correct theoretical interpretation of the new phenomena that he observed. He made many contributions to aerodynamics and aerodynamic measurements, as listed by science historian Peter Krehl [Krehl 2009, p. 1118]:

> Ernst Mach, who had planned supersonic ballistic experiments several years before Prof. Peter Salcher, an Austrian physicist at the Imperial Navy, eventually succeeded in photographing them (1886). Mach immediately gave a correct interpretation of the head wave and the lines emanating from projectile surfaces. These supersonic flow phenomena were later connected with his name, such as the *Mach angle*, *Mach cone*, *Mach head wave*, *Mach line*, and *Mach wave*. Furthermore, Mach also studied the oblique interaction of shock waves, thereby discovering irregular reflection (*Mach reflection effect*) and the origin of a new shock wave (*Mach disk*, *Mach front*, *Mach stem*), which since the 1940s has stimulated worldwide research activities to better understand this puzzling "Mach effect."

In addition to his work in aerodynamics, Ernst Mach made important contributions to many other unrelated fields, as explained by aerodynamics expert and historian John D. Anderson, Jr. [Anderson 1997, pp. 375–376]:

> Mach entered the University of Vienna, where he excelled, spurred by interest in mathematics, physics, philosophy, and history. In 1860 he received a Ph.D. in physics, with a thesis entitled "On Electrical Discharge and Induction." By 1864 he was a professor

> of physics at the University of Graz. (The variety and depth of his intellectual interests were attested by the fact that he was offered, but turned down, a chair in *surgery* at the University of Salzburg, preferring to go to Graz.) In 1867, Mach became a professor of experimental physics at the University of Prague, a position he would occupy for the next 28 years.
>
> In the modern technological world, engineers and scientists are virtually forced to concentrate their efforts in narrow areas of specialization, but in Mach's time one could still contemplate the Renaissance man, and Mach was a supreme generalist. A listing of Mach's contributions and writings would include works on physical optics, the history of science, mechanics, philosophy, the origins of relativity theory, supersonic flow, thermodynamics, the sugar cycle in grapes, the physics of music, and classical literature. He even wrote on world affairs: one of Mach's papers commented on the "absurdity committed by the statesman who regards the individual as existing solely for the sake of the state," which provoked strong criticism from Lenin. We can only regard him with awe and envy, for Mach, in the words of the American philosopher William James, knew "everything about everything."

For some of Ernst Mach's other accomplishments, see pp. 298, 307, 874, and 878. For some of his son Ludwig Mach's other accomplishments, see p. 1029.

Like Ernst Mach, Ludwig Prandtl (German, 1875–1953) was enormously talented at both experimental methods of measuring aerodynamic effects and theoretical methods of explaining those effects. Yet whereas Mach divided his time among several other unrelated fields, Prandtl spent his long career focused on aerodynamics, building the most advanced wind tunnels in the world from 1907 onward, and discovering and calculating a wide range of aerodynamic phenomena (Figs. 9.16–9.17, 9.42). *Encyclopedia Britannica* labelled Prandtl the "father of aerodynamics" [EB 2010]:

> German physicist who is considered to be the father of aerodynamics. [...]
>
> Prandtl made decisive advances in boundary-layer and wing theories, and his work became the fundamental material of aerodynamics. He was an early pioneer in streamlining dirigibles, and his advocacy of monoplanes greatly advanced heavier-than-air aviation. He contributed the Prandtl-Glauert rule for subsonic airflow to describe the compressibility effects of air at high speeds. In addition to his important advances in the theories of supersonic flow and turbulence, he made notable innovations in the design of wind tunnels and other aerodynamic equipment. He also devised a soap-film analogy for analyzing the torsion forces of structures with noncircular cross sections.

PRINCIPES GÉNÉRAUX
DU MOUVEMENT DES FLUIDES.
PAR M. EULER.

I.

Ayant établi dans mon Mémoire précedent les principes de l'équilibre des fluides le plus généralement, tant à l'égard de la diverſe qualité des fluides, que des forces qui y puiſſent agir ; je me propoſe de traiter ſur le même pied lè mouvement des fluides, & de rechercher les principes géneraux, ſur lesquels toute la ſcience du mouvement des fluides eſt fondée. On comprend aiſément que cette matiere eſt beaucoup plus difficile, & qu'elle renferme des recherches incomparablement plus profondes : cependant j'eſpère d'en venir auſſi heureuſement à bout, de ſorte que s'il y reſte des difficultés, ce ne ſera pas du côté du méchanique, mais uniquement du côté de l'analytique: cette ſcience n'étant pas encore portée à ce degré de perfection, qui ſeroit néceſſaire pour déveloper les formules analytiques, qui renferment les principes du mouvement des fluides.

II. Il s'agit donc de découvrir les principes, par lesquels on puiſſe déterminer le mouvement d'un fluide, en quelque état qu'il ſe trouve, & par quelques forces qu'il ſoit ſollicité. Pour cet effet examinons en détail tous les articles, qui conſtituent le ſujet de nos recherches, & qui renferment les quantités tant connues qu'inconnues. Et d'abord la nature du fluide eſt ſuppoſée connue, dont il faut conſidérer les diverſes eſpeces : le fluide eſt donc, ou incompreſſible, ou compreſſible. S'il n'eſt pas ſuſceptible de compreſſion, il faut diſtinguer deux cas, l'un où toute la maſſe eſt compoſée de parties homogenes, dont la denſité eſt partout & demeure toujours la même, l'au-
tre

Euler equations for fluid flow

$$\overbrace{\frac{\partial \rho}{\partial t}}^{\text{Change in mass}} + \overbrace{\nabla\cdot(\rho\mathbf{v})}^{\text{Mass outflow}} = \overbrace{0}^{\text{Conserved}}$$

Continuity equation (differential form)

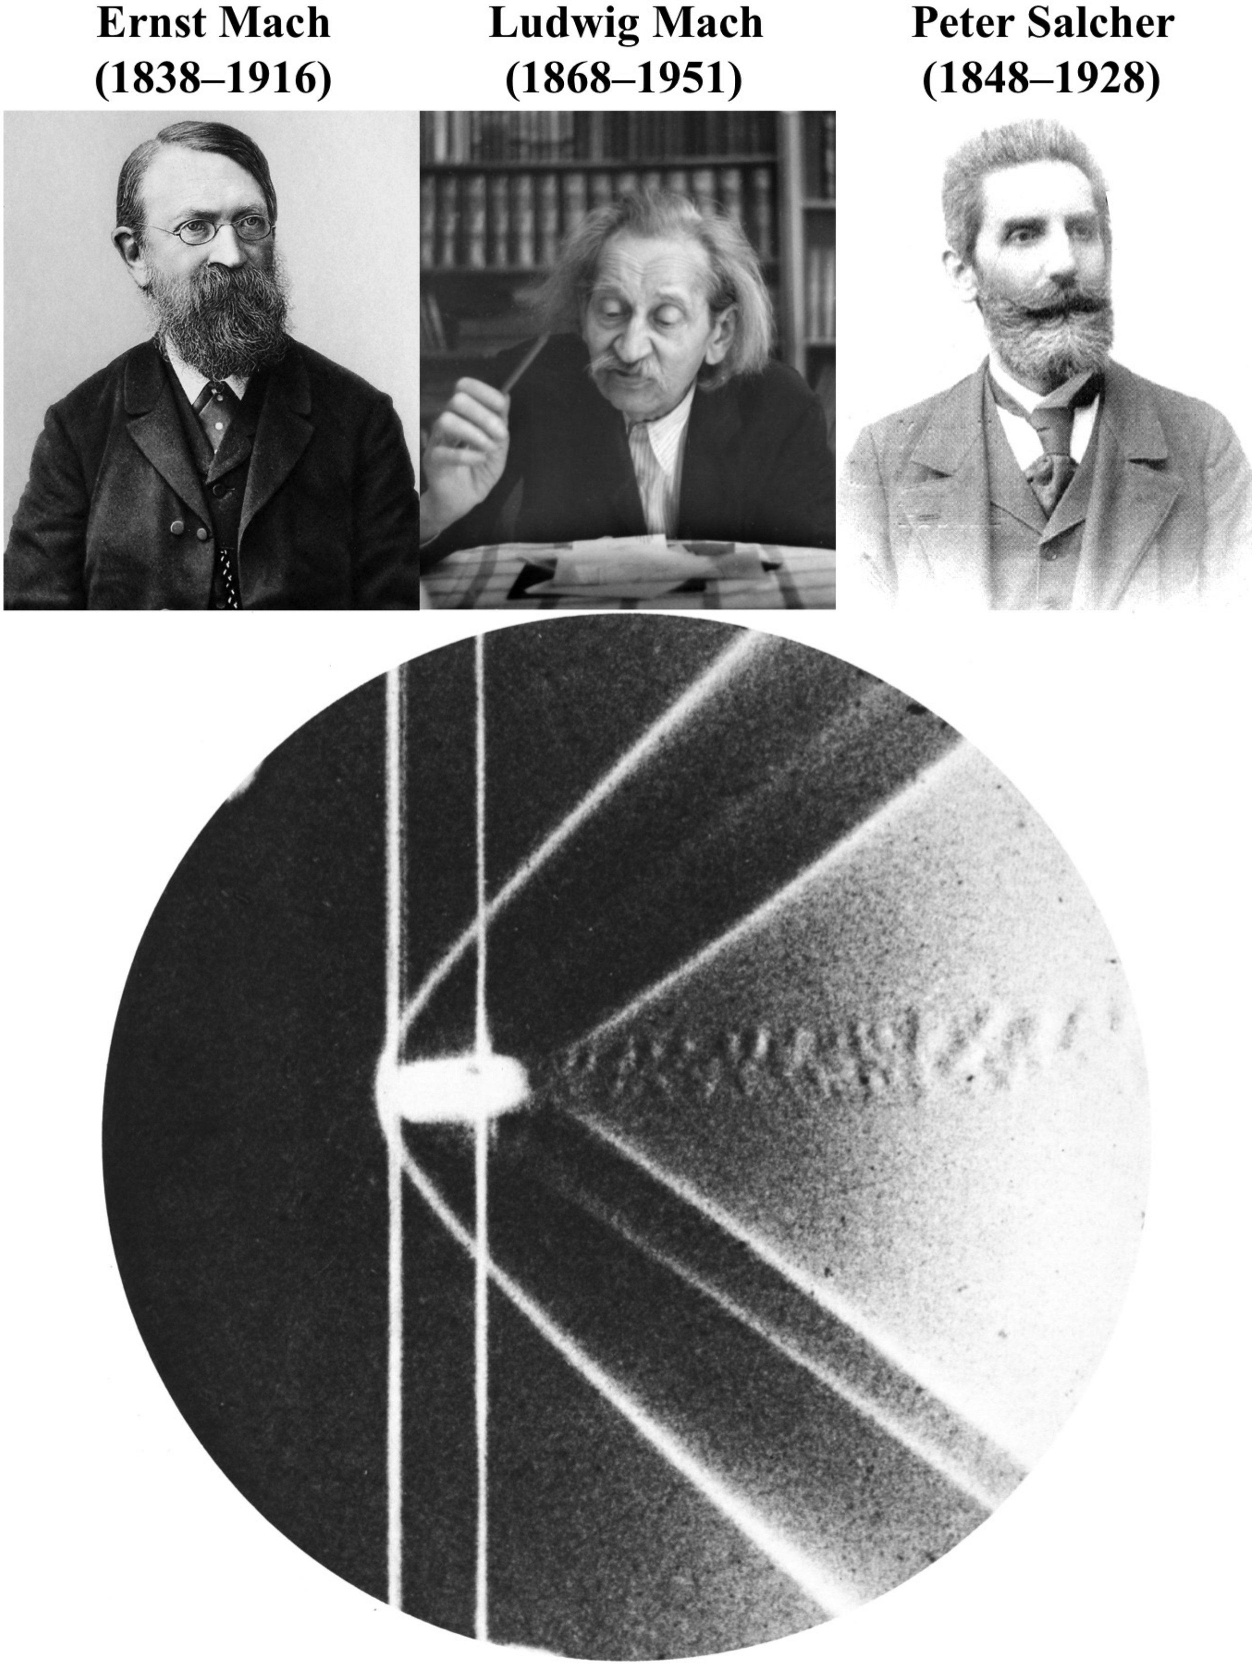
$$\overbrace{\rho\left(\frac{\partial}{\partial t}+\mathbf{v}\cdot\nabla\right)\mathbf{v}}^{\text{Mass}\,\times\,\text{acceleration}} = \overbrace{\rho\mathbf{g}}^{\substack{\text{Gravitational}\\ \text{force}}} - \overbrace{\nabla p}^{\substack{\text{Pressure}\\ \text{force}}} + \overbrace{\mathbf{F}_{\text{viscous}}}^{\substack{\text{Viscous}\\ \text{forces}}}$$

Momentum equation (differential form)

$$\overbrace{\frac{\partial}{\partial t}\left[\rho\left(u+\frac{v^2}{2}+gH\right)\right]}^{\text{Change in energy}} + \overbrace{\nabla\cdot\left[\rho\left(u+\frac{v^2}{2}+gH\right)\mathbf{v}\right]}^{\text{Energy outflow}}$$
$$= \underbrace{\dot{q}_{\text{input}}}_{\substack{\text{Input heat}\\ \text{energy}}} + \underbrace{\dot{w}_{\text{input}}}_{\substack{\text{Input work}\\ \text{energy}}} - \underbrace{\nabla\cdot(p\mathbf{v})}_{\substack{\text{Output work energy}\\ \text{by expanding pressure}}} + \underbrace{\phi_{\text{viscous}}}_{\substack{\text{Input energy from}\\ \text{friction with surroundings}}}$$

Energy equation (differential form)

Figure 9.14: Leonhard Euler developed the more general Euler equations for fluid flow, and published them in 1757.



Ernst Mach
(1838–1916)

Ludwig Mach
(1868–1951)

Peter Salcher
(1848–1928)

Figure 9.15: Ernst Mach, his son Ludwig Mach, and Peter Salcher conducted the first experiments to visualize shock waves around a bullet traveling faster than the speed of sound through air.

Ludwig Prandtl (1875–1953), the "father of aerodynamics"

Photographed in 1904 with a water canal for fluid mechanics measurements, shortly before he began building a series of world-leading wind tunnels

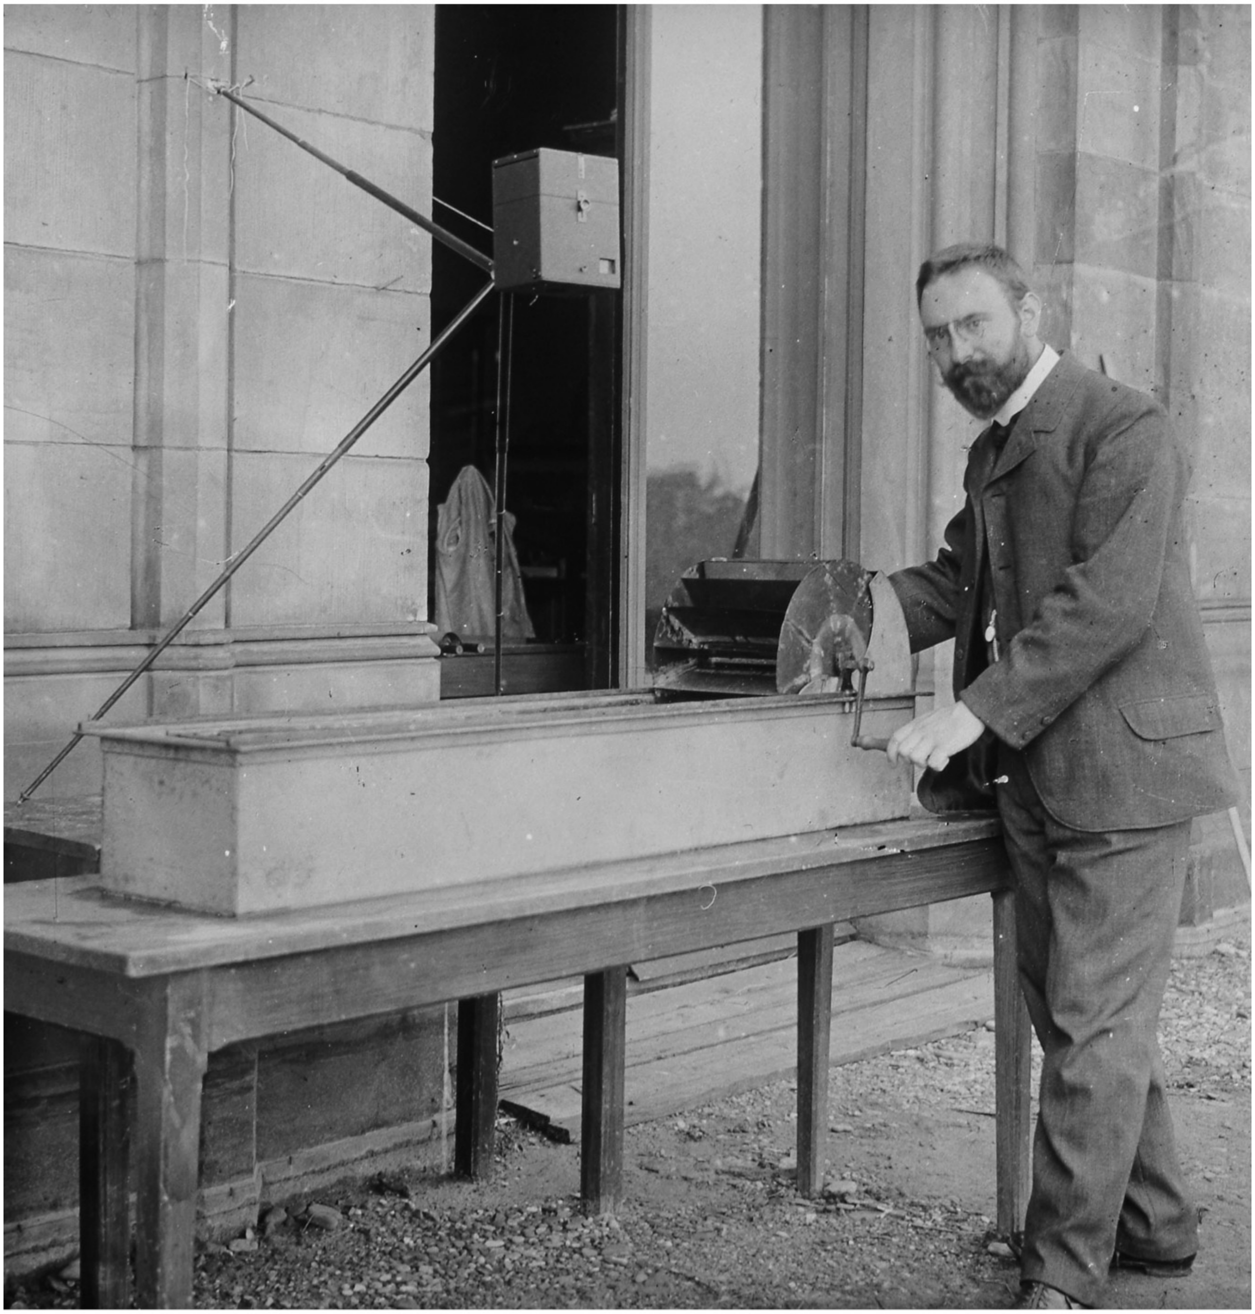


Figure 9.16: Ludwig Prandtl was the "father of aerodynamics." In this 1904 photograph, he was using a water canal for fluid mechanics measurements, shortly before he began building a series of world-leading wind tunnels.

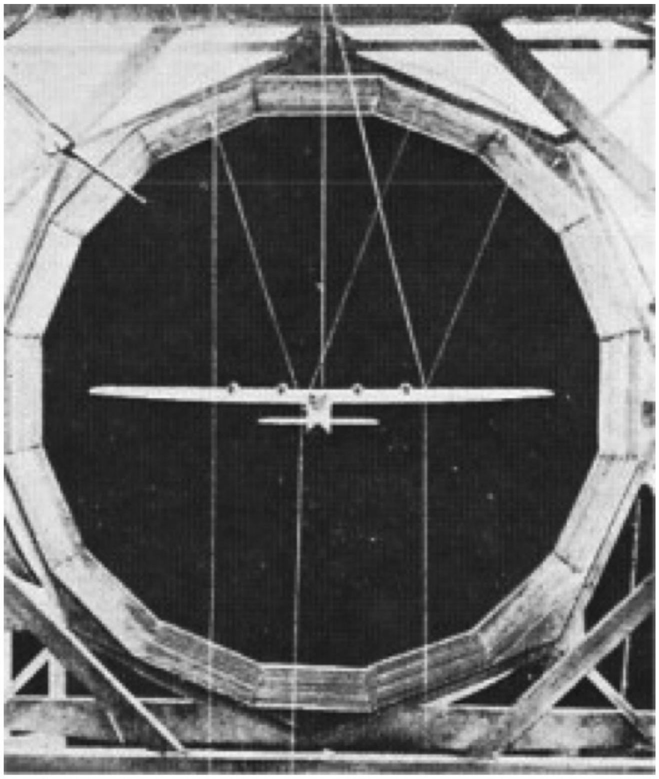
**Aerodynamische
Versuchsanstalt
(AVA) Göttingen
subsonic
wind tunnel
(1907 onward)**

**Designed and run
by Ludwig Prandtl
and his students
and collaborators**



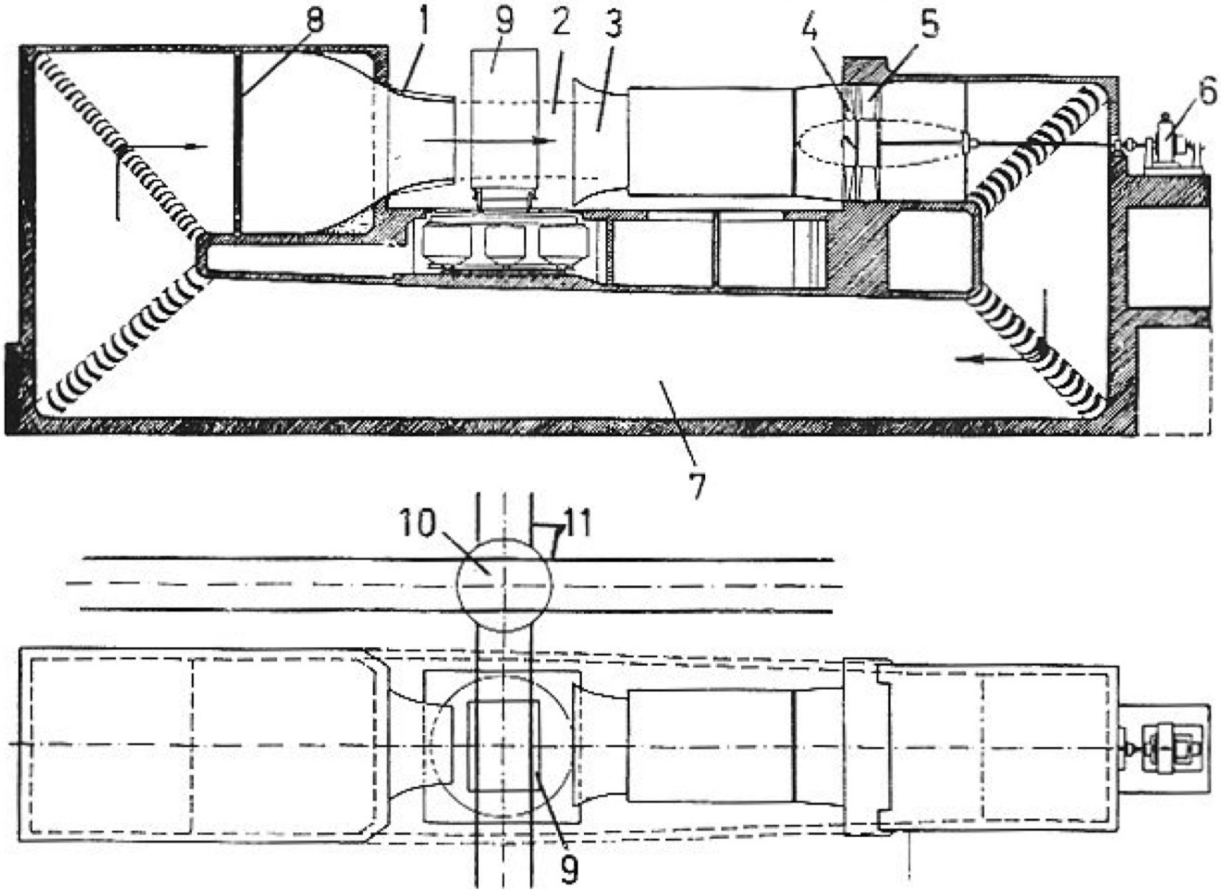


Figure 9.17: Ludwig Prandtl and his students and collaborators designed and operated the Aerodynamische Versuchsanstalt (AVA) subsonic wind tunnel at Göttingen from 1907 onward [http://www.histaviation.com].

During his several decades at the Aerodynamische Versuchsanstalt (AVA) at Göttingen University, Prandtl was also a prolific teacher and mentor for countless students and lab assistants who themselves went on to make major contributions to aerodynamics, wind tunnel experiments, and other aspects of aerospace engineering. Looking at all the resulting innovators and innovations, one gets the impression that most of the field of aerodynamics can be traced to Prandtl and/or his students.[5] [See Eckert 2017 for much more information on Prandtl.]

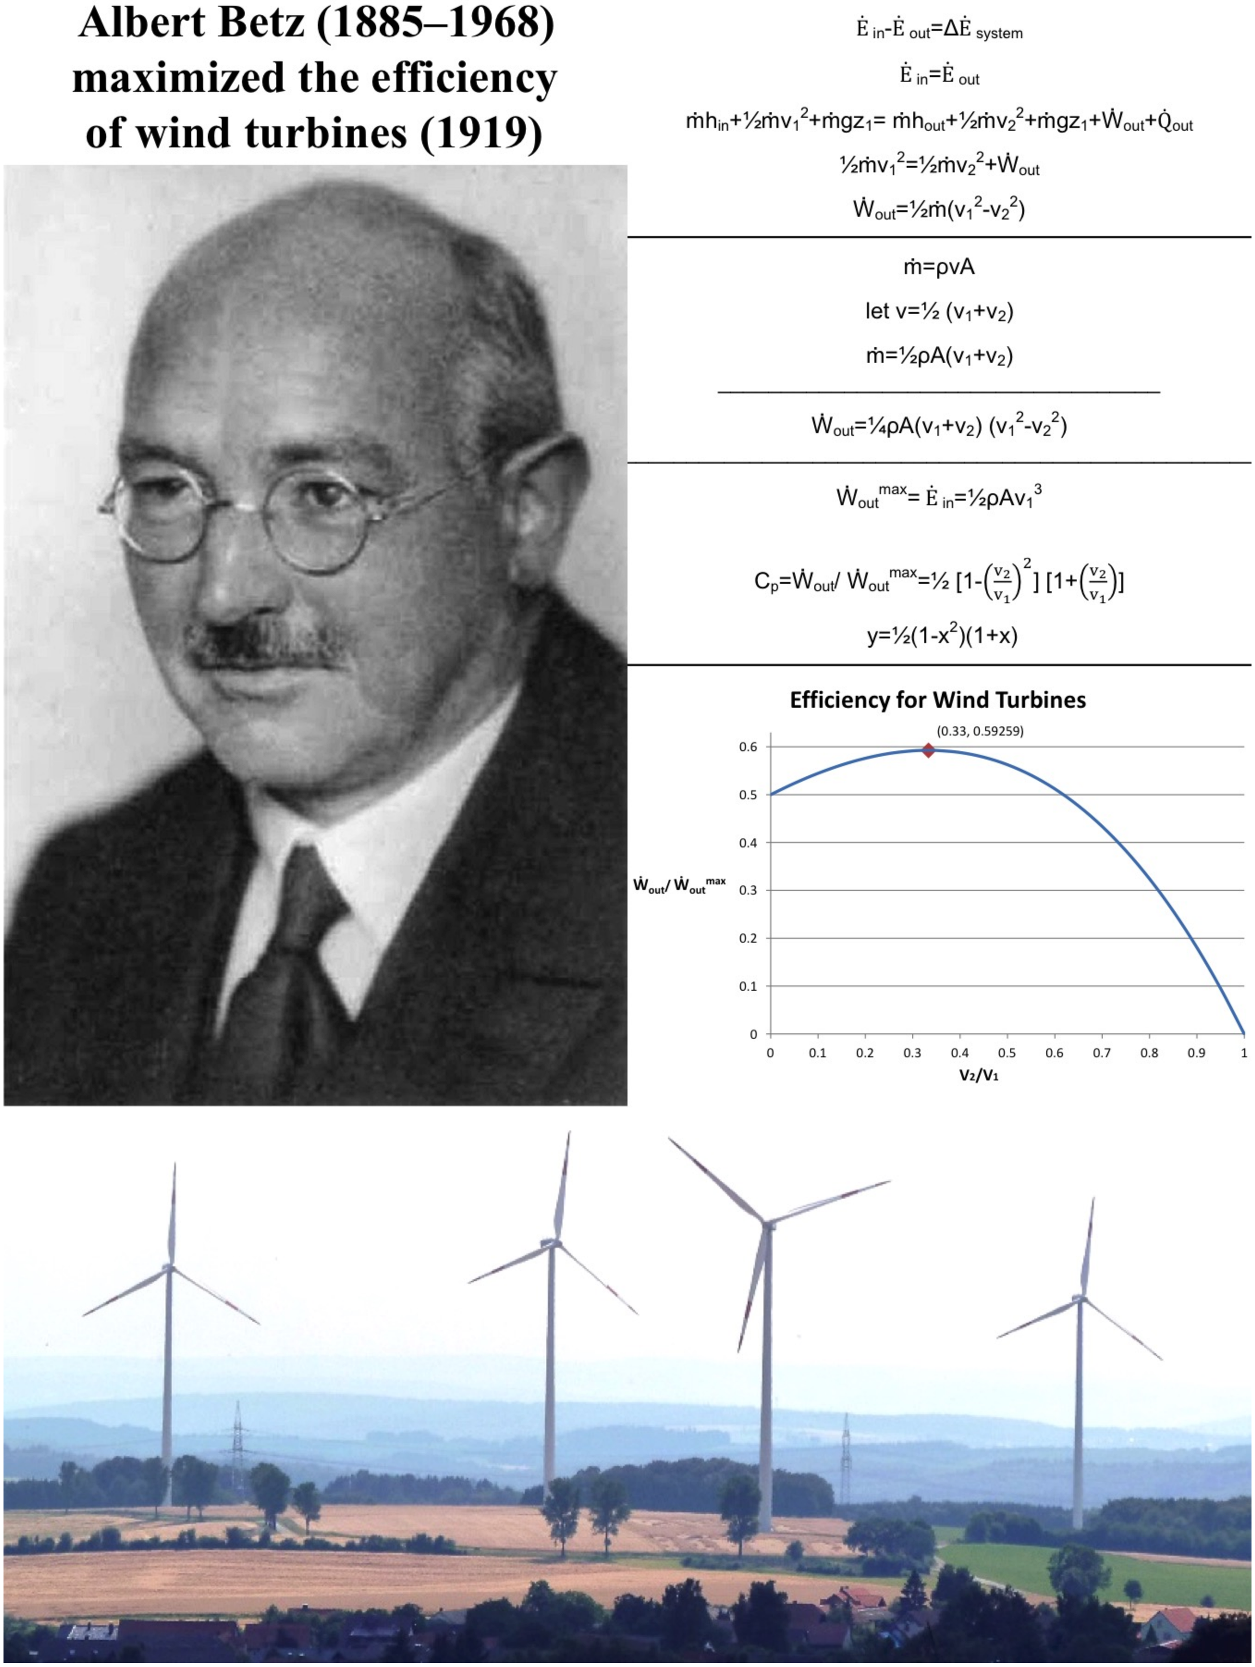
Albert Betz (German, 1885–1968) was one of Prandtl's students, continued to work with Prandtl at the AVA after that, and eventually succeeded Prandtl as director of the AVA. In 1919, Betz applied the principles of aerodynamics to calculate the efficiency of power-producing wind turbines and to design wind turbine blades with the highest possible efficiency (Fig. 9.18). Such wind turbines are now used all over the world. Betz made many other contributions to aerodynamics over his career, including working on the AVA wind tunnels, testing and implementing Adolf Busemann's designs for swept-back aircraft wings (p. 1696), and developing axial flow compressor blades for jet engines (p. 1733).

The early wind tunnels that were constructed by Ludwig Prandtl and his students were subsonic, producing wind speeds slower than the speed of sound (Fig. 9.17). Subsonic wind tunnels have continued to be used worldwide to test the aerodynamics of subsonic aircraft, automobiles, models of buildings, etc. For example, Fig. 9.19 shows the Deutsche Forschungsanstalt für Luftfahrt (DFL) subsonic wind tunnel at Braunschweig-Völkenrode that began operation in 1940. It was so large that whole aircraft could be tested in it, instead of subscale models.

Max Munk (German, 1890–1986) studied aircraft wing (airfoil) design and wind tunnel design under Ludwig Prandtl and graduated from Göttingen University in 1918 with two Ph.D. degrees, in both physics and mathematics. In 1920, he moved to the United States. In 1921, he designed the Variable Density Tunnel at the NACA (later NASA) Langley Research Center (Fig. 9.20). He completed that subsonic wind tunnel in 1923 and oversaw its operation for several years. Munk's wind tunnel was so advanced compared to other apparatus then available in the United States that it was used until the 1940s, when it was superseded by new German-designed wind tunnels.

---

[5] One should also note the work of Frederick Lanchester (English, 1868–1946), a contemporary of Prandtl who had some similar insights in aerodynamics but unfortunately was not able to find much support for them within the British system at the time.



Albert Betz (1885–1968) maximized the efficiency of wind turbines (1919)

$$\dot{E}_{in}-\dot{E}_{out}=\Delta\dot{E}_{system}$$

$$\dot{E}_{in}=\dot{E}_{out}$$

$$\dot{m}h_{in}+\tfrac{1}{2}\dot{m}v_1^2+\dot{m}gz_1=\dot{m}h_{out}+\tfrac{1}{2}\dot{m}v_2^2+\dot{m}gz_1+\dot{W}_{out}+\dot{Q}_{out}$$

$$\tfrac{1}{2}\dot{m}v_1^2=\tfrac{1}{2}\dot{m}v_2^2+\dot{W}_{out}$$

$$\dot{W}_{out}=\tfrac{1}{2}\dot{m}(v_1^2-v_2^2)$$

$$\dot{m}=\rho vA$$

let $v=\tfrac{1}{2}(v_1+v_2)$

$$\dot{m}=\tfrac{1}{2}\rho A(v_1+v_2)$$

$$\dot{W}_{out}=\tfrac{1}{4}\rho A(v_1+v_2)(v_1^2-v_2^2)$$

$$\dot{W}_{out}^{max}=\dot{E}_{in}=\tfrac{1}{2}\rho Av_1^3$$

$$C_p=\dot{W}_{out}/\dot{W}_{out}^{max}=\tfrac{1}{2}\left[1-\left(\frac{v_2}{v_1}\right)^2\right]\left[1+\left(\frac{v_2}{v_1}\right)\right]$$

$$y=\tfrac{1}{2}(1-x^2)(1+x)$$

Max Munk
(1890–1986)
Designed the
Variable Density Tunnel
at the NACA Langley
Research Center (1921)

Figure 9.20: Max Munk, one of Prandtl's former students and assistants, immigrated to the United States. In 1921 he designed the best U.S. wind tunnel at that time, the Variable Density Tunnel at the NACA Langley Research Center. It began operation in 1923 and was used until the 1940s, when it was superseded by new German-designed wind tunnels.

In 1917, Prandtl designed the first supersonic wind tunnel, capable of producing wind speeds faster than the speed of sound. Unfortunately World War II and the financial impacts of Allied reparations payments in the 1920s prevented Prandtl from immediately finding the support and resources necessary to build supersonic wind tunnels. When more funding became available in the early 1930s, there was a boom in building supersonic wind tunnels in the German-speaking world.

Jakob Ackeret (Swiss, 1898–1981, p. 1696), one of Prandtl's protégés, began operating a supersonic wind tunnel at ETH Zurich in 1933. It was initially capable of attaining wind speeds up to Mach 2. The ETH Zurich wind tunnel facility has been repeatedly upgraded over the years and is still in operation.

Rudolf Hermann (German, 1904–1991, Fig. 9.24) and Carl Wieselsberger (German, 1887–1941, Fig. 9.25), former students of Prandtl, built a wind tunnel at the Technical University of Aachen that could achieve wind speeds up to Mach 3.

In 1936, Rudolf Hermann designed the Heeresversuchsanstalt (HVA) supersonic/hypersonic wind tunnel for the German army's rocket program (Fig. 9.21). The HVA wind tunnel was the most advanced facility of its type in the world at that time. It was run by Hermann Kurzweg (German, 1908–2000, Fig. 9.24) and his team at Peenemünde during the period 1939–1943, moved to Kochel for 1943–1945 to avoid Allied bombing, and taken to the U.S. Naval Ordnance Laboratory in 1945. The HVA tunnel could attain a range of speeds up to Mach 5.2. In 1944, it attained Mach 9.5 after being modified. Rudolf Hermann's wind tunnel was critically important for the development of rockets such as the A-4 (V-2), and he was rewarded for it along with Wernher von Braun and other top members of the rocket team (p. 5384).

Prandtl and his collaborators began operated a supersonic wind tunnel at the AVA in 1938. In 1955 at the AVA, Hubert Ludwieg (German, 1912–2000, Fig. 9.24), yet another former student of Prandtl, created what became known as the Ludwieg tube, a wind tunnel capable of speeds from Mach 3 to Mach 12.

At the end of World War II, the very advanced Zitteraal wind tunnel was under construction at Ötztal, Austria, as shown in Fig. 9.22. After the war, it was taken to Modane, France, where it formed the basis of the ONERA (Office National d'Etudes et de Recherches Aérospatiales) wind tunnel laboratory. It is still in use there and still the largest of its kind.

In all, there were over 70 subsonic, transonic, supersonic, and hypersonic wind tunnels in the greater German-speaking world at the end of World War II. Many aircraft companies, military laboratories, and universities had important wind tunnel facilities. Most of those wind tunnels were seized by Allied forces and taken to the United States, United Kingdom, France, and Soviet Union, along with vast amounts of aerodynamic information and most of the experts on aerodynamics and wind tunnels.

As presented in Figs. 9.23–9.25, some other creators who developed wind tunnels and/or analyzed their results included:

Hans Amtmann (German, 1906–2007), aircraft and rocket design

Paul Richard Heinrich Blasius (German, 1883–1970), boundary layers

Carl Cranz (German, 1858–1945), ballistics and high-speed diagnostics

Siegfried Erdmann (German, 1916–2002), supersonic and hypersonic wind tunnels

Irmgard Flügge-Lotz (German, 1903–1974), aerodynamic control systems

Kurt Otto Friedrichs (German, 1901–1982), fluid dynamics and theory of elasticity

Georg Fuhrmann (German, 18??–19??), subsonic wind tunnel design/measurements

Erich Groth (German, 19??–19??), high-speed aerodynamics and aircraft design

Axel Kolb (German, 1917–2009), aerodynamics and wind tunnels

Klaus Oswatitsch (Austrian, 1910–1993), hypersonic aerodynamics

Hermann Schlichting (German, 1907–1982), boundary layers

Walter Tollmien (German, 1900–1968), boundary layers

Otto Walchner (German, 19??–19??), supersonic and hypersonic aerodynamics

Peter Wegener (German, 1917–2008), supersonic and hypersonic wind tunnels

Theodor Wilhelm Zobel (German, 1906–1953) worked on high-speed aerodynamics, wind tunnels, tests of Otto Frenzl's supersonic area rule (p. 1701), and Schlieren interferometry measurement systems for wind tunnels, first in Germany during the war and then in the United States after the war (Fig. 9.26). Hans Amtmann, another German aerospace expert who came to the United States in Operation Paperclip, eulogized Zobel [Amtmann 1988, pp. 115–116]:

> Dr. Theodor Zobel, former chief of the high-speed aerodynamic section of the Aerodynamic Research Center in Brunswick. He developed the Schlieren Interferometer, an optical measuring device to measure the flow of air around an airfoil without disturbing the flow. This was one of the most important contributions to supersonic research. His work saved the United States several years of expensive research time.

Theodore von Kármán (Hungarian, 1881–1963) earned his Ph.D. under Prandtl in 1908, worked on aerodynamics in Germany and Austria until 1930, and then moved to the United States. From then until the end of his life, Von Kármán was a tireless advocate trying to persuade the United States to improve its funding and level of research for wind tunnels, aerodynamics, and other aspects of aerospace engineering (Fig. 9.27). At the end of World War II, he served as a top U.S. government advisor guiding the transfer of German-speaking scientists and technologies to the United States, working closely with U.S. Army Air Forces General Henry Arnold (p. 2204).

In February 1963, near the very end of von Kármán's life, President John F. Kennedy awarded the first U.S. National Medal of Science to von Kármán (Fig. 9.27) and praised the importance of his work [https://www.jfklibrary.org/asset-viewer/archives/JFKPOF/042/JFKPOF-042-040]:

> Gentlemen, Dr. von Kármán, it is a great pleasure for me to select you as the first recipient of the National Medal of Science. I know of no one else who more completely represents all of the areas with which this award is appropriately concerned—science, engineering, and education.
>
> This Nation, and indeed the entire free world, holds you in the highest esteem and respect for your devoted service, for your scientific achievements, and for your warmly human gifts as a teacher and counsellor. Your assistance to the United States Air Force and to the NATO Advisory Group for Aeronautical Research and Development have been outstanding. We also are deeply indebted to you for your continuing efforts in the promotion of international cooperation in science and in engineering.
>
> It is hard to visualize what the world would be like without aircraft and jet propulsion, or without the vision we have, just entering the realm of reality, of exploring space. I am especially glad to present this first National Medal of Science to one of the pioneers who has helped make all of this new and exciting age possible.

Many creators who were primarily mathematicians also made important contributions to methods of solving complex aerodynamics equations. See for example:

Martin Wilhelm Kutta (German, 1867–1944), p. 830

Richard von Mises (Austro-Hungarian, 1883–1953), p. 831

John von Neumann (Hungarian, 1903–1957), p. 831

Carl Runge (German, 1856–1927), p. 833

Karl Hermann Amandus Schwarz (German, 1843–1921), p. 833

9.2.3 Specialized Aircraft

Using the principles of aerodynamics, German-speaking engineers developed a wide range of aircraft that were specialized for various applications, and aircraft following those general designs have been used around the world. This section only presents a few examples, although many more could be cited.

Some major aircraft designers are shown in Figs. 9.28–9.29.

Claude Dornier (German, 1884–1969, Fig. 9.28) was most famous for his company's 12-engine Dornier Do X flying boat (first flight 1929), which had multiple decks, luxury accommodations, and room for over 150 people (Fig. 9.30). He also designed the Dornier Do 17 light bomber (1934) and numerous other aircraft throughout his long career. After World War II, Dornier worked in France, Spain, Switzerland, and West Germany.

German-speaking engineers invented dedicated ground-attack aircraft with the pilot and engines protected inside an armored "bathtub":

- In 1917, Otto Mader (German, 1880–1944, Fig. 9.29) and Hugo Junkers (German, 1859–1935, Fig. 9.28) created the first armored ground-attack aircraft, the Junkers J.I (Fig. 9.31). Hugo Junkers built a wide range of aircraft until his death, and his company played a major role in the development of jet engines after his death.

- The Henschel company introduced the Hs 129 armored ground-attack aircraft in 1939, and ultimately equipped it with a 7.5 cm automatic antitank gun in 1944 (Fig. 9.32). In this final configuration, the Hs 129 was the most powerful tank-killing aircraft in the world at the time.

- The Junkers company appears to have designed an even more advanced armored ground-attack aircraft to succeed the Hs 129 [Herwig and Rode 2003, pp. 36–37]. Aviation historians should thoroughly search archives to find more information on this design, how far it progressed during the war, and how much it (and the Hs 129) influenced the U.S. A-10 Thunderbolt II three decades later.

During World War I, Anton Fokker (Dutch, 1890–1939) and Reinhold Platz (German, 1886–1966) designed and mass-produced very effective early fighter aircraft, including the Fokker Eindecker E.III monoplane (1915), Doppeldecker D.VII biplane (1918), and Dreidecker Dr.I triplane (1917). See Fig. 9.33.

Robert Thelen (German, 1884–1968), the chief designer of Albatros-Flugzeugwerke, also created biplane fighter aircraft during World War I (Fig. 9.34). Today the Albatros and Fokker fighters are best remembered as the preferred vehicles of the "Red Baron" Manfred von Richthofen (German, 1892–1918).

As shown in Fig. 9.35, Willy Messerschmitt (German, 1898–1978) and Robert Lusser (German, 1899–1969) developed the Messerschmitt Bf 109 piston-propeller fighter aircraft by 1935. The Bf 109's performance and features were a major step beyond earlier fighters, and the Bf 109 was extensively used by Germany until 1945.

The Messerschmitt Bf 109 seems to have strongly influenced the design of the British Supermarine Spitfire, which appeared as a first prototype in 1936 and began production in 1938. Beverley Shenstone, the head aerodynamics expert for the Spitfire design, had previously worked in Germany [Cole 2012, 2015].

Edgar Schmüd (German, 1899–1985), an aircraft designer, immigrated to the United States in 1931 and went to work for North American Aviation. Using his knowledge, details of the German Bf 109 and the German-inspired Spitfire, and other German design information, Schmüd developed the North American P-51 Mustang piston-propeller fighter in 1940. Subsequently the P-51 was widely used by the United States and United Kingdom during the war. The extreme similarity of Schmüd's 1940 P-51 design to Messerschmitt's 1935 Bf 109 design is evident in Fig. 9.35. In fact, the P-51 so closely resembled the Messerschmitt Bf 109 that at least one P-51 was shot down by Allied forces who mistook it for a Bf 109, and the other P-51s had to be painted with yellow bands on the wings to distinguish them from Bf 109s [Ray Wagner 2000, p. 94]. The resemblance throughout the design was so uncanny that even one of the P-51's own test pilots mistakenly believed that Schmüd must have been one of the designers of the original Bf 109 [Ray Wagner 2000, p. 104].

In 1947, Schmüd likewise developed the North American F-86 Sabre jet fighter based directly on the wartime Messerschmitt Me P.1101 and Focke-Wulf Ta 183 jet fighters (see p. 1775). Schmüd also developed the North American F-100 Super Sabre (1953), the Northrop F-5 Freedom Fighter (1959), and the Northrop T-38 Talon trainer (1959, widely used by NASA for astronaut training) [Ray Wagner 2000].

German-speaking engineers developed specialized gliders for military troops and cargo. Due to the gliders' speed, agility, and low noise, they were used for a number of highly creative and successful assaults during World War II. Some major examples included (Fig. 9.36):

- The Deutsche Forschungsanstalt für Segelflug DFS 230, which was designed by Hans Jacobs (German, 1907–1994, Fig. 9.28) and first flew in 1937.
- The Gotha Go 242, which was designed by Albert Kalkert (German, 1902–1977, Fig. 9.29) and first flew in 1941. (There is some evidence that suggests that Kalkert may have been involved in building or trying to build a Horten H.XVIII flying wing intercontinental bomber during the war—see pp. 5227–5231).
- The Messerschmitt Me 321 Gigant, which first flew in 1941.

The Arado Ar 232, first flown in 1941, was the world's first special-purpose cargo aircraft, establishing now-standard features such as a rear cargo ramp, low boxy fuselage, high wing, high tail, and rugged landing gear. It was followed in 1942 by the Junkers Ju 290, designed by Konrad Eicholtz (German, 18??–19??, Fig. 9.28), and the Messerschmitt Me 323 Gigant (the largest land-based cargo aircraft in the world at the time—only the Blohm & Voss BV 238 flying boat was larger). See Fig. 9.37.

German-speaking creators also produced aircraft with highly creative airframe designs. Two examples (among many others that could be cited) were the asymmetrical Blohm & Voss BV 141 reconnaissance aircraft (1938), designed by Richard Vogt (German, 1894–1979, p. 1682), and the twin-boom Focke Wulf Fw 189 Uhu reconnaissance aircraft (1938), designed by Kurt Tank (German, 1898–1983, p. 1682). See Fig. 9.38. Vogt was famous for the wide range of unusual aircraft designs he produced during the war, and he worked for the U.S. Air Force, Curtiss-Wright, and Boeing after the war. Tank designed fighter aircraft at Focke-Wulf during the war, and after the war developed a wide range of aircraft and missiles in Argentina, India, and West Germany.

Even German designs that were not actually built during World War II continued to exert a strong influence on aircraft that were built long after the war. For example, Richard Vogt's 1944 design for the Blohm & Voss P 202 oblique wing aircraft directly inspired the design of the NASA AD-1 oblique wing aircraft, which was first flown in 1979 (Fig. 9.39). As shown in Fig. 9.40, Vogt's 1945 outboard tail swept-wing design for the Blohm & Voss P 212 (and the rest of his P 208–215 design series from 1944–1945) similarly appears to have directly inspired the design of the Virgin Galactic SpaceShipTwo, which made its first suborbital flight in 2018.

9.2.4 High-Speed Aircraft Design

Much of the German-speaking work before, during, and after World War II focused on the best aerodynamic shapes of aircraft wings and bodies. The best shapes and their performance characteristics depend on the speed of aircraft through the air, or equivalently the speed of airflow around the aircraft.

An airfoil is a cross-section through an aircraft wing along the direction of incoming flow (Fig. 9.41). Airfoils are usually cambered, with asymmetric upper and lower surfaces. For an angle of attack α between a surface and incoming flow, the force normal to the surface may be separated into drag and lift components. A cambered airfoil produces zero lift at a negative angle of attack $\alpha_{L=0}$, linearly increasing lift for increasing angles of attack, and decreasing lift (stalling) above α_{stall}. Its drag is much smaller but increases parabolically.

At very low speeds, airflow is not especially compressible—its density remains approximately constant. However, at higher and higher speeds, airflow becomes more and more compressible; the air gets squished when it suddenly runs into an object. No later than 1922, based on wind tunnel data and his own theoretical derivations, Ludwig Prandtl discovered mathematical rules that describe compressible flow around subsonic aircraft (Fig. 9.42). In 1928, Hermann Glauert (English, 1892–1934) independently (apparently) rediscovered Prandtl's equations for compressible flow around subsonic aircraft, so in the English-speaking world those equations are often called the Prandtl–Glauert transformation or method. (Incidentally, although Glauert was born in England, his parents were both German.)

In 1925, Jakob Ackeret (Swiss, 1898–1981), who was one of Prandtl's assistants at that time, found a way to extend Prandtl's compressible flow equations to cover supersonic speeds. Ackeret himself had a long and distinguished career in aerodynamics and wind tunnel experiments.

In 1935, Adolf Busemann (German, 1901–1986) used the compressible flow rules to design swept-wing aircraft. Busemann realized that the faster an aircraft goes, the more swept-back its wings should be, in order to maximize the aerodynamic lift and minimize the drag from the wings. Hubert Ludwieg confirmed the efficiency of the swept-wing design in wind tunnel tests, and then Albert Betz incorporated swept-back wings into several Messerschmitt aircraft. By the end of World War II, numerous German aerospace vehicles employed the swept-wing design (see for example pp. 1770, 1773–1775, 1842, 1912, 1922, 1926–1931), in stark contrast to Allied aircraft that continued through 1945 to use less efficient wings that stuck straight out to the sides. After the war, Busemann and other German-speaking aerodynamics experts helped to produce swept-wing aircraft, supersonic aircraft, and spacecraft in the United States.

Figure 9.42: Ludwig Prandtl discovered subsonic compressible-flow rules for aircraft in 1922, Jakob Ackeret extended them to supersonic speeds in 1925, and Adolf Busemann designed swept-wing aircraft in 1935.

Winglets (wing tips bent up and/or down) improve the efficiency of wings by reducing wing-tip vortices, the undesirable leakage of higher-pressure air below the wing to the lower-pressure region above the wing. The abstract idea of winglets dates back to even before powered flight (e.g., they are mentioned in an 1897 patent by Frederick Lanchester), but most of their experimental development and demonstration appears to have been conducted in the German-speaking world in the 1920s through the early 1940s. They were actively utilized in German aircraft such as the Hamburger Flugzeugbau Ha 137 (designed by Richard Vogt, first flown in 1935) and the Heinkel He 162 jet fighter (designed by Alexander Lippisch and others, first flown in 1944). See Figure 9.43. Some other examples of early German aircraft or aircraft designs with winglets included the Espenlaub-Lippisch E2 (1921), Fieseler F 3 Wespe (1932), DFS 193 (1936), Gotha Go 147 (1936), Lippisch Delta I (1930), Lippisch Delta III (1934), Lippisch Delta IV (1936), Lippisch Delta V (1937), etc.[6]

In 1940, Bernhard Göthert (German, 1907–1988) and K. A. Kawalki (Polish?, 19??–19??) developed and demonstrated supercritical airfoils or wings that enabled aircraft to travel at higher speeds with less drag, and ultimately to break the sound barrier with less difficulty (Fig. 9.44). Normally, the curvature of an airfoil makes airflow above the wing faster than flow below it, which in turn makes the air pressure lower above the airfoil that below it, creating a net upward lift force on the airfoil that keeps the aircraft aloft. For aircraft at high subsonic speeds, this effect can accelerate air above the wings to the speed of sound, creating a strong shock wave, a separated boundary layer, and higher drag. By making the upper surface of the wings flatter or supercritical, aircraft can travel closer to the speed of sound before high-drag transonic flow occurs. After the war, Göthert came to the United States, where he became chief scientist of the Air Force Systems Command and helped to develop everything from the Saturn V rocket to the F-111 fighter [https://www.latimes.com/archives/la-xpm-1988-04-01-mn-489-story.html].[6]

---

[6] Despite abundant documentation for the invention, development, and demonstration of winglets, supercritical airfoils, and the area rule by these German-speaking creators, many history books [e.g., Anderson 1997] erroneously assign credit for all of these creations to a much later American, Richard Whitcomb (1921–2009). Whitcomb only had a bachelor's degree in engineering, but he seems to have had great ambitions to advance in his career. Whitcomb took a job at the NACA (later NASA) Langley Research Center where many of the German-speaking aerodynamics experts worked or visited after the war, and he stayed there until he chose early retirement in 1980.

After the war, Adolf Busemann worked at the Langley Research Center and gave detailed presentations summarizing earlier German work and knowledge about supersonic aerodynamics. Whitcomb is known to have attended at least one of Busemann's major talks on that topic in 1951. It appears that Whitcomb learned of the area rule from Busemann (or other German sources, such as the huge amount of documentation that NACA received on wartime German work—e.g., p. 1702) and then wrote a paper in 1952 announcing it as his own new discovery [Mack 1998, p. 138]. The principle has been known as the "Whitcomb area rule" ever since. Proper credit was not given to Frenzl and his colleagues who had actually developed and tested it a decade earlier, or even to scientists such as Busemann and Theodore von Kármán who guided the transfer of German aerodynamics knowledge to the United States.

Whitcomb also claimed and received credit for first developing supercritical airfoils in the 1960s. Recognition was not given to Göthert and Kawalki who had actually invented and demonstrated supercritical airfoils over 20 years earlier, or to the other German-speaking aerodynamics experts involved in transferring the information to the United States.

Then in the 1970s, Whitcomb claimed and received credit for developing winglets. Once again, no recognition was given to the German-speaking aerodynamics experts who had actually conducted or transferred that work.

For all of his alleged inventions, Whitcomb was showered with national awards and became a department head at the Langley Research Center. Most of the German-speaking creators who had actually developed, demonstrated, and transferred those technologies died in obscurity.

Downward folding wingtips for compression lift appear similar to winglets but serve a different purpose. Folding wingtips (such as those on the XB-70 Valkyrie, pp. 1754–1755) catch part of the shock waves of a supersonic aircraft and increase the under-wing pressure to increase lift. Officially that was discovered in the United States in the 1950s. Yet that feature was already present in wartime German jet designs (e.g., Heinkel He P.1078 A and B versions, p. 5224) and it resurfaced in the XB-70, which was heavily reliant on German expertise (p. 1750). More archival research should be conducted to determine how much work on compression lift was conducted in wartime Germany, and how much that work influenced postwar projects in the United States and other countries.

Otto Frenzl (Austrian, 1909–1996) discovered the area rule for supersonic flight in 1943 and filed a patent on it with aircraft designers Heinrich Hertel (German, 1901–1982) and Werner Hempel (German, 1910–??). If airflow moving near or above the speed of sound longitudinally down a vehicle encounters a sudden change in the vehicle's cross-sectional area, the flow cannot easily move out of the way; it is forcibly compressed or rarified and may separate from the vehicle's surface or create a shock wave. By keeping the cross-sectional area relatively constant down the length of a vehicle, one can avoid such effects and thereby minimize the drag coefficient. For example, an aircraft's body should begin to narrow at the point where wings begin, as shown in Fig. 9.45. This was a critical discovery for creating aircraft that could easily break the sound barrier to move from subsonic to supersonic speeds. After the war, Frenzl and Hertel developed aircraft in France and West Germany, and Hempel worked for the Soviet Union. Theodor Zobel confirmed the area rule in wartime Germany and continued his work in the United States after the war (Fig. 9.26).[6]

The advantages of blunt leading surfaces for atmospheric reentry, in order to create detached shock waves and reduce vehicle heating, were discovered, analyzed, and advocated by Rudolf Hermann (German, 1904–1991, Fig. 9.24), Adolf Busemann (Fig. 9.42), and Gottfried Guderley (German, 1910–1997, Fig. 8.36) during World War II [NARA RG 319, Entry NM3-82, Box 1568, HEC 842]. This information was transferred to U.S. and U.K. officials in 1945–1946 interrogations of the German experts, and it was subsequently exploited in postwar U.S. and U.K. aerospace programs. See Figs. 9.46–9.47.[7] Most conventional English-language histories erroneously ascribe the original discovery of these principles to Harry Julian Allen, an American bureaucrat at NACA, in the 1950s [e.g., Anderson 1997], long after the actual discovery and official transfer.

Sighard Hoerner (German, 1906–1971, Fig. 9.48) conducted aerodynamics research in Germany during World War II and in the United States after the war. He strongly promoted the use of advanced German aerodynamics insights and aircraft design principles in the postwar United States.

Alexander Lippisch (German, 1894–1976, Fig. 9.49) applied high-speed aerodynamics to aircraft design and had an enormous impact over his long career. He proposed and strongly advocated for delta-wing designs, winglets, and tailless aircraft, and he influenced other wartime designs (such as those of the Horten brothers, pp. 1768, 1773–1774) and postwar designs (such as the Avro Vulcan, p. 5226). He also invented and demonstrated rocket planes (pp. 1920, 1922–1923, 1926).

Similarly, Hans Multhopp (German, 1913–1972, Fig. 9.49) applied the principles of high-speed aerodynamics to develop very advanced prototype jet aircraft (such as the Focke-Wulf Ta 183, p. 1775) in Germany during the war, and jet fighters and lifting bodies (subscale prototypes for the later U.S. Space Shuttle—see p. 1933) in the United States after the war.

Dietrich Küchemann (German, 1911–1976) and Johanna Weber (German, 1910–2014), shown in Fig. 9.50, also did extensive work on supersonic aerodynamics during World War II. After the war, they both moved to the United Kingdom and played key roles in the postwar development of supersonic aircraft such as Concorde passenger plane and Victor jet bomber, as well as subsonic aircraft such as the Airbus A300.

---

[7] Figures 9.46–9.47 show excerpts from HEC 842, rough notes made by the Allied interrogators of the German experts. The German experts clearly specified a blunt nose with a detached shock, and the Allied interrogators revealed their own ignorance by continuing to draw a sharp nose. Can the more polished final Allied reports be found? Can the original German documents be found? The initial German discovery was Rudolf Hermann's experimental measurements of the best reentry vehicle shapes for German long-range missiles in the hypersonic wind tunnel of the Heeresversuchsanstalt. Adolf Busemann and Gottfried Guderley provided the theoretical analysis and applications of those results.

INTELLIGENCE REPORT

Bower

From The Military Attache, London, England. DATE 11 Dec. 1946.

Subject GERMAN RAM JET RESEARCH.

Source Halstead Exploitation Center Publication BIOS/Gp.2./HEC 842. Eval. B-2

Area Reported On - Germany.

329947

SUMMARY: This document consists of rough notes taken by a number of American scientists while interviewing a number of German scientists working in the field of jet propulsion. Some of the subjects covered are theory of the aero-pulse engine (such as the propulsion of the V-1 "flying bomb"), design and combustion theory of ram jets, ram jet-assisted shells and supersonic aerodynamics.

COMMENTS - Among the German scientists interviewed was Dr. Busemann. He is now at the National Physical Laboratory in U.K. (working under British supervision), where Mr. Hayes of the North American Avation Company recently interviewed him. Hayes' comments on Busemann's work were forwarded in M.A.London R4414-46. A translation of Busemann's review of ballistics theory was forwarded in M.A.London R5126-46.

Although the attached report is unclassified this report is classified "Secret" because of the information in the above comments.

This report will be of interest to the Ordnan ce Ballistic Research Laboratory, GALCIT - ORDCIT, Army Air Forces, U.S.Navy Bureaus of Ordnance and Aeronautics and N.A.C.A.

In connection with the problem of the curved shock wave existing in front of a cone that has a blunt angle, Hermann made tests at Peenemuende and plotted the distance; the shock was ahead of the point against the cone angle for various constant M'nos. and found that the extrapoled curve did not point at a zero distance for the predicted maximum angle at which the shock would come off the nose as it had for the wedge. Busemann has calculated a much more complete set of cases for the Taylor-Mc. Call cone presented in the memorial issue of the "Luftfahrtforschung" for a Mr. Wieselsberger.

Guderley believes that he can solve the problem of the flow behind a curved shock ahead of a blunt profile by obtaining a solution in the hodograph plane for the sub-sonic portion in an expansion of a hypergeometric function and continuing the supersonic flow by the method of characteristics.

9.3 Jet Engines and Jet Aircraft

During the 1930s and early 1940s, German-speaking scientists and engineers developed the first practical jet engines (Section 9.3.1) and installed them in a wide variety of revolutionary aircraft (Section 9.3.2). After the war, experts, hardware, and designs from the German-speaking world spread those jet technologies around the world. That German expertise provided the modern world with jet-powered passenger planes, fighters, and bombers, as well as closely related gas turbine engines that are used in power plants and in land and sea vehicles.[8]

9.3.1 Jet Engines

A turbojet engine (Turbinen-Luftstrahltriebwerk or TL in German) is a type of gas turbine engine that forcibly sucks in air, burns it with fuel, extracts a little energy from the process (turbo for turbine) to power the air intake, and expels the rest of the energy out the back with a high-speed, high-temperature exhaust (jet). Because the exhaust has both a large mass flow rate and a large velocity, its new rearward momentum is large, and hence it imparts a large forward thrust force to the engine, potentially larger than the thrust of a comparable propeller engine. However, because so much of the combustion energy ends up as kinetic and thermal energy in the exhaust and not as new forward kinetic energy of the aircraft, at moderate flying speeds the energy (fuel) efficiency of a turbojet is much lower than that of a propeller engine. Figure 9.51 shows the components and idealized gas pressures and temperatures in a typical turbojet engine:

- The diffuser impedes the incoming flow to slow it down, converting the initial kinetic energy of the flow to increased pressure (potential energy) and temperature (thermal energy).

- Since passive stagnation effects only cause a small increase in pressure even at high subsonic speeds, turbojet engines include an active, powered compressor that forcibly raises the pressure (and temperature) of the flow, thereby preparing the air to burn more efficiently with fuel in the subsequent burner section. (The compressor can also be viewed as actively sucking air into the engine, even if the external air speed is negligible, as it is when the aircraft is first started.) Typical axial compressor designs use alternating rotating and stationary blades (rotors and stators) as shown in the figure to squeeze the air as it passes through.

Times* 1945-06-29; NYT 1945-06-08, 1945-07-26 p. 6, 1948-04-15 p. 17, 1948-12-04 p. 3; *Washington Post* 1945-06-29.

- The burner or combustion chamber (combustor) burns the incoming air with a much smaller amount of fuel to raise the temperature of the flow as high as possible without melting the blades in the subsequent turbine section.

- The turbine must extract enough work energy out of the gas after the burner to put the necessary work energy into powering the compressor before the burner.

- The nozzle decreases the pressure of the flow until it reaches the ambient pressure of the external air, converting that initial high-pressure potential energy into kinetic energy to maximize the exhaust velocity.

- Optionally, an afterburner can add extra fuel to the air just before the nozzle. Burning that extra fuel raises the pressure entering the nozzle and hence the thrust force produced by the engine, albeit at the expense of consuming fuel even faster than a plain turbojet engine would.

While a turbojet is a very powerful and compact engine, the propulsive efficiency of a turbojet is relatively low at subsonic aircraft speeds, since the engine's exhaust velocity is so high. To raise the efficiency of a turbojet engine for subsonic travel, it can be directly coupled to a large fan for airplane flight (a turbofan), propeller blades for airplane flight (a turboprop), or rotor blades for helicopter flight (a turboshaft engine), as shown in Fig. 9.52.

In a turbofan or bypass engine (Zweistrom-Turbinen-Luftstrahltriebwerk or ZTL in German), the inlet air can pass either through a relatively conventional turbojet engine (sometimes called the hot flow since it is heated by combustion), or else through a large enclosed fan (sometimes called the cold flow since it does not experience combustion). The bypass ratio β is defined as the ratio of the mass flow rates in the cold and hot flows. Compared to a pure turbojet engine, more of the exhaust energy in this turbojet is extracted in the turbine and less in the nozzle, which decreases the hot flow exhaust velocity. Because the turbine extracts more energy, it can power not only the compressor for the hot flow, but also the fan for the cold flow. The fan may be an enlarged front compressor blade through which both hot and cold flows pass, or it may be a separate blade whose speed has been appropriately geared down from the main turbine shaft. As the cold flow is merely accelerated by a fan and not heated by combustion to high temperatures, its exhaust velocity is rather low. Thus both the hot and cold fractions of the flow have lower exhaust velocities than the exhaust of a simple turbojet, improving the propulsive efficiency of the engine and lowering the fuel consumption rate.

Whereas the fan of a turbofan engine can operate at high-subsonic and supersonic speeds, at lower subsonic speeds it may be replaced by an ordinary airplane propeller, further increasing the efficiency. The propeller is still driven by the turbine of a turbojet engine, so this variation is called a turboprop engine (Propeller-Turbinen-Luftstrahltriebwerk or PTL in German). A turbojet engine designed for this purpose extracts almost all of the available exhaust energy in the turbine and not the nozzle, in order to send as much power as possible to the propeller. The propeller typically has a much larger diameter than the compressor and turbine blades, yet its tips should not approach the speed of sound to avoid compressibility losses. Therefore, a gearbox usually gears down power transmitted from the turbine shaft to a separate propeller shaft that rotates ~ 15 times more slowly. Turboprop engines are basically turbofan engines with a very high bypass ratio ($\beta > 50$) so that the large majority of the thrust comes from the cold propeller flow and not the hot turbojet flow. Because of their efficiency, they are widely used to power small, low-subsonic-speed aircraft.

Just as the shaft power from a turbojet engine can be geared down to drive an airplane propeller, it can also be geared down to power a helicopter rotor. This variation is called a turboshaft engine. The power shaft may be taken from either the compressor end (as shown in the figure) or the turbine end. In addition to aerospace applications, turboshaft gas turbine engines make excellent power sources for other machines ranging from military tanks to submarines to electric power plants.

At supersonic speeds (say Mach ∼2–3), the pressure increase due to stagnation effects in the diffuser is so large that there is no need for an active compressor, and thus there is also no need for a turbine to power a compressor, as shown in Fig. 9.53. Under these conditions, with the moving parts inside a turbojet removed, the engine becomes a much simpler ramjet. To operate at hypersonic speeds (Mach 5 and higher), the interior contours of the engine can be modified to make it a supersonic combustion ramjet (scramjet). A ramjet engine can even be modified to operate at subsonic speeds where the stagnation compression is relatively small, becoming a pulsejet whose operation continually alternates between air intake and air combustion.

Beginning in the nineteenth century, a long line of German-speaking creators invented, built, demonstrated, and improved gas turbine engines, first for stationary power applications or land vehicles and ultimately for aircraft. Some of the key early figures included:

- Franz Stolze (German, 1836–1910) began developing gas turbine engines in the 1860s and continued building test models and filing patents into the early 1900s (Fig. 9.54).
- Joseph Wertheim (German, 1834–1899) filed patent applications on gas turbine engines beginning in 1876 (Fig. 9.55).
- Christian Bröker (German, 18??–19??) filed patent applications on gas turbine engines in 1889 (Fig. 9.56).
- Aurel Stodola (Austro-Hungarian Slovak, 1859–1942) developed gas turbine engines from the 1890s through the 1930s (Figs. 9.57–9.58).
- Hans Holzwarth (German, 1877–1953) filed a large number of patent applications on gas turbine engines from around 1900 through the 1930s (Fig. 9.59). He built the first fully functional gas turbine engine in 1906 and later founded his own company that manufactured and sold gas turbine engines for industrial power production.
- Wilhelm Pape (German, 18??–19??) filed many patent applications on gas turbine engines from the 1910s through the 1920s (Fig. 9.60).
- Karl Röder (German, 1881–1965) filed numerous patent applications on gas turbine engines and built working versions from the 1910s through the 1930s (Fig. 9.61). As a professor at the University of Hannover, he also taught younger gas turbine engineers.
- Karl Enders (German, 18??–19??) filed a patent application on gas turbine engines in 1925 (Fig. 9.62).
- Oscar Hart (German, 18??–19??) and Joseph Hetterich (German, 18??–19??) filed a patent application on gas turbine engines in 1925 (Fig. 9.63).
- Hermann Oberth (Austro-Hungarian, 1894–1989), best known for his work on rockets (Section 9.7.1) and early space station designs (Section 9.10.2), also created very early designs for jet engines. He filed a patent application on gas turbine engines for aircraft in 1925 (Fig. 9.64).

Some engineers outside the German-speaking world also proposed or worked on early gas turbine engines, although they tended to be fewer in number, more isolated, and often less able to find the support and resources required to fully realize their ideas. Some noteworthy figures were Ægidius Elling (1861–1949) in Norway, Gustaf de Laval (1845–1913) and the brothers Birger Ljungström (1872–1948) and Fredrik Ljungström (1875–1964) in Sweden, Maxime Guillaume (1888–19??) and René Anxionnaz (1894–19??) in France, and Charles Parsons (1854–1931) in the United Kingdom.

Franz Stolze

PROVISIONAL SPECIFICATION.

Improvements in Hot Air Engines.

I, Franz Stolze, of 23, Eichen Allee, Berlin-Westend, Germany, Doctor of Philosophy, do hereby declare the nature of this invention and the manner in which it is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention relates to certain improvements in hot air engines. Heretofore the compression and expansion cylinders of hot air engines were made use of to drive compressed air into the boiler, where it was heated and from whence it was conducted into the expansion cylinder to therein do its work.

As the compression as well as the heating in the boiler cannot be carried beyond a certain limit on account of the wear on the machinery, the cylinders and the pistons had to be made of very large dimensions, with the result that the friction increased in proportion to the gain in piston surface.

The employment of inner boiler heating, although often tried, has not been found as profitable as expected on account of the getting hot of the lubricants, which absolutely necessitates water cooling and on account of the imperfect combustion even with liquid and gaseous fuel. Solid fuel, even powdered coal, cannot be made use of, as all experiments, to do away with the solid particles in the smoke have met with a negative result.

My new engine has for its object the drawing out of all the caloric power out of the fuel by doing away with the friction between the working parts and by making innoxious all solid products of combustion in case solid fuel in the internal furnace is used.

In order to attain this end, I provide systems of compression and expansion turbines in place of the ordinary compression and expansion cylinders.

The number of single turbines, making up a system and being mounted upon the same shaft, varies according to requirements. In front of each working wheel a rigid guide wheel is arranged. If compressed air now enters into such a system of turbines the latter will rotate in a sense opposite to the direction of the lower ends of the turbine blades. If however the shaft is turned by some means in the same direction as lie the lower ends of the turbine blades, the system sucks in air through the outer or first turbine.

Such a compression turbine system is to be connected with a hot air furnace, having inner firing; the compressed air is pressed into the furnace, heated and then conducted to a correspondingly larger system of expansion turbines. The latter will be rotated and will rotate in its part the compression turbine system aforesaid. The air having increased in volume by the heating process will now have a certain surplus of energy, which can be made use of in any desirable manner. The two turbine systems preferably run on the same shaft, when friction will be done away with almost entirely. Turbines do not need to be packed, only the shaft would have to run through a stuffing box. If however the two turbine systems are mounted upon the same shaft, no stuffing box is needed and the shaft runs in an airtight casing. A disk mounted upon the shaft between the two systems of turbines and being also

EIDGEN. AMT FÜR GEISTIGES EIGENTHUM

PATENTSCHRIFT

Patent Nr. **2050** 13. Dezember 1889, 3 Uhr, p. Klasse 93

CHRISTIAN BRÖKER, in MANNHEIM.

Einrichtung für Gas- oder Wassermotoren.

Der Gas- oder Wassermotor gegenwärtiger Erfindung besitzt ein grosses Schwungrad, auf dessen Umfang in annähernd tangentialer Richtung die Kraft der Explosion des Gases, oder die Kraft des Wasserdruckes wirkt, um das Rad in Rotation zu versetzen und mit einer daran befestigten Riemenscheibe die Kraft auf Arbeitsmaschinen u. drgl. zu übertragen.

Es ist auf der Zeichnung:

Fig. 1 die Seitenansicht des Gasmotors;

Fig. 2 die Vorderansicht desselben theilweise im Schnitt;

Fig. 3 die Ansicht der Steuerungsmechanismen etc.;

Fig. 4 der Vertikalschnitt durch den Wassermotor;

Fig. 5 die Vorderansicht desselben theilweise im Schnitt;

Fig. 6 die Ansicht der Steuerungsmechanismen etc.

Der Gas- oder Wassermotor hat eine Grundplatte mit einem Ständer A, in welchem ein horizontalliegender Zapfen B, Fig. 4, befestigt ist, um den sich das Schwungrad C mit der Riemenscheibe D dreht. Das Schwungrad C hat an seinem Umfang drei Kammern C^1. Die Kanten desselben sind eingeschnitten und der unten auf der Bodenplatte zum Heben und Senken eingerichtete Steuerkasten ist mit seiner oberen Fläche dem Umfang des Schwungrades angepasst. Auf der Nabe des Schwungrades ist zum Heben und Senken und Steuern die Nasenscheibe F mit Feder und Nut verschiebbar befestigt. Auf derselben sitzt auch ein Zahnrad E für den Gasmotor, um mit einer Pumpe Gas und Luft anzusaugen und das Gemisch durch das Schlauchrohr G in den Steuerkasten einzudrücken.

Die Mischung tritt aus dem Kanal H durch eine Bohrung H^1 zu dem Drehschieber J, welcher derselben bei entsprechender Stellung den Einlass in den Explosionsraum C^1 gestattet, worin die Mischung entzündet und so das Schwungrad C herumgedreht wird. Das Drehschiebergehäuse wird während einer Umdrehung des Schwungrades mit drei Explosionsräumen C^1 drei Mal gehoben und gesenkt und es erfolgt dieses durch die mit drei Nasen versehene auf der Schwungradnabe verschiebbar sitzende Scheibe F, welche durch den Hebel F^1 mit der Zugstange F^2 die auf der Drehschieberachse sitzende Kurbel K dreht, womit auch die auf derselben Achse sitzenden Hebel K^1 und K^2 gedreht werden, von welchen der nach unten stehende Hebel K^1 mit einer Stange L^1 die mit zwei Kurbeln L verbundene Stange L^2 verschiebt und dadurch die Achsen L^3 der Kurbeln L dreht, auf welchen Axen je zwei Exzenternasen L^4 angebracht sind, die den Drehschieberkasten heben, um ihn während des Einströmens des Gasgemisches und der Explosion luftdicht an das rotirende Schwungrad zu drücken und ihn darauf wieder davon zu entfernen, damit möglichst wenig Reibung verursacht wird; der Drehschieberkasten führt sich bei seiner Auf- und Abbewegung an vier auf den Grundplatten befestigten senkrechten Stiften M. Der nach oben stehende Hebel K^2 ist durch eine Stange mit dem auf der Achse des Auslassdrehschiebers N sitzenden Hebel K^3 verbunden, so dass auch dieser Drehschieber N gleichzeitig geöffnet und geschlossen wird. Die verbrannten explodirten Gase treten durch die Oeffnung N^1 des Kastens und durch den Drehschieber N in den Kasten und werden durch ein Schlauchrohr N^2 abgeleitet.

Die Pumpe wird durch die Zahnräder E, E^1 angetrieben, indem an letzterem ein Kurbelzapfen sitzt, an welchem die Kurbelstange E^2 eingreift u. s. w.

Der Regulator besteht aus einer in der Rinnenscheibe D laufenden Kugel D^1, welche mit dem Hebel D^2 beweglich an den Hebel D^3 angehängt ist. Letzterer ist auf der durch die Achse B zentral hindurchgehenden Stange R befestigt, welche hinten ein Segment R^1 trägt, das an seiner Unterfläche einen schrägen Einschnitt für einen in denselben eingreifenden Stift R^2 hat, welcher durch die Drehung der Stange R hin- oder hergeschoben wird und dadurch mit der durch den Ständer A gehenden Stange R^3 und der Gabel F^3 die Nasenscheibe F auf der Nabe des Schwungrades C verschiebt, so dass die Nasen derselben nicht auf den Hebel F wirken können und die Explosionen ausbleiben, wenn das Schwungrad C zu schnell rotirt und die Kugel D^1 in der Rinnenscheibe D aus ihrer normalen Lage mitgerissen wird.

Die Zündung erfolgt mittelst einer aussen am Schiebergehäuse brennenden Flamme J^1, welche durch einen kurzen Kanal in den Explosionsraum C^1 hineinschlägt, wenn das Schiebergehäuse gehoben wird.

Der Wassermotor, Fig. 4, 5, 6, hat dieselben Anordnungen wie der Gasmotor, nämlich ein um den Zapfen B sich drehendes Schwungrad C mit drei Druckräumen C^1, einen sich hebenden und senkenden Steuerkasten und denselben Regulator D^1, um dem Zufluss des Wassers vorzubeugen, wenn das Schwungrad zu schnell rotirt. Der Ständer A wird als Windkessel benutzt. Das Wasser tritt durch ein Ventil in den Windkessel und in das Steuergehäuse ein, wirkt bei geöffnetem Drehschieber J im Druckraum C^1 des Schwungrades C und fliesst darauf durch das Gehäuse und das Schlauchrohr U ab. Eine Pumpe und die dazu gehörigen Maschinentheile sind nicht vorhanden, jedoch sind zum Heben und Senken des Schiebergehäuses und zum Drehen des Schiebers J dieselben Mechanismen wie vorher angewendet, d. i. die auf der Schwungradnabe verschiebbare Exzenterscheibe F, die damit bewegten Hebel F^1, F^2 und K, zum Drehen des Schiebers J, und die damit bewegten Hebel K^1, L^1, L^2 und L, zum Heben und Senken des Steuerkastens mittelst der Exzenternasen L^4, ferner in Verbindung mit der Regulatorkugel D^1 die Gabel F^3 zum Verschieben der Scheibe F auf der Nabe des Schwungrades C, um bei zu schnellem Gang der Maschine den Wasserzufluss abzustellen.

Zum Betrieb der Maschine können auch Wasserdampf oder andere Dämpfe verwendet werden.

PATENT-ANSPRÜCHE:

1. Eine Einrichtung für Gas- oder Wassermotoren, bestehend aus einem um einen festen Zapfen B rotirenden mit Druckräumen C^1 versehenen Schwungrad C, in Verbindung mit einem Drehschiebergehäuse, das sich hebt und senkt, was durch die auf der Schwungradnabe verschiebbar sitzende Nasenscheibe F mittelst der Hebel F^1, F^2, der Kurbeln K, K^1, L und der Nasenexzenter L^4 geschieht, womit auch der Drehschieber J geöffnet und geschlossen wird;
2. Bei der durch Anspruch 1 gekennzeichneten Motoreinrichtung die in der Rinnenscheibe D laufende Regulatorkugel D^1, welche bei zunehmender Rotationsgeschwindigkeit die durch den festen Zapfen B hindurchgehende Stange R und damit das Segment R^1 dreht, welches mit einer schrägen Nute den in derselben befindlichen Stift R^2 der Stange R^3 bewegt und dadurch mit der Gabel F^3 die Scheibe F verschiebt.

Brennkraftturbine.

Patentiert im Deutschen Reiche vom 19. August 1923 ab.

Es ist gelegentlich schon vorgeschlagen worden, bei Brennkraftturbinen eine Mehrzahl von Verpuffungskammern im Kreise anzuordnen und dabei mittels eines Rundschiebers die Zufuhr von Gasgemisch und Spülluft zu den Verpuffungskammern zu regeln. Erfindungsgemäß soll nun bei einer derartigen Turbine der Rundschieber so ausgebildet werden, daß den Einlaßöffnungen der Verpuffungskammern eine senkrecht oder nahezu senkrecht zur Turbinenwelle stehende Fläche des Rundschiebers zugeordnet ist, während sich zu beiden Seiten zylindrische Abdichtungsflächen befinden. Die den Auslaßöffnungen der Kammern für Gasgemisch und Spülluft zugeordnete Schieberfläche kann dabei gleichfalls eine senkrecht oder nahezu senkrecht zur Turbinenwelle stehende Fläche sein oder auch eine zylindrische Fläche. In jedem Fall wird durch die senkrechte oder nahezu senkrechte Anordnung der den Verpuffungskammern zugeordneten Schieberfläche erreicht, daß die Zuführung von Gasgemisch und Spülluft in günstiger Weise mittels verhältnismäßig kurzer Kanäle erfolgen kann.

In der Zeichnung sind zwei Ausführungsbeispiele der Erfindung veranschaulicht.

Nach Abb. 1 ist *a* eine der in größerer Anzahl im Kreise angeordneten Verpuffungskammern, *b* ein Ringkammer für Gasgemisch und *c* eine solche für Spülluft. Zwischen den beiden Ringkammern *b*, *c* und den Verpuffungskammern *a* befindet sich ein Rundschieber *d*, der auf der Turbinenwelle sitzt und sowohl auf der den Verpuffungskammern *a* zugekehrten Seite als auf der den Ringkammern *b*, *c* zugekehrten Seite eine senkrecht zur Turbinenwelle stehende Fläche aufweist. Dieser Rundschieber *d* besitzt im übrigen über eine bestimmte Länge des Umfanges Schlitze *e*, *f*, durch die beim Betriebe der Turbine die Verpuffungskammern mit den Ringkammern *b*, *c* derart in Verbindung kommen, daß jeweils Spülluft und Verbrennungsgase nacheinander in die Verpuffungskammern eintreten. Während der Zeitdauer der Verpuffung selbst werden die Verpuf-

Mehrstufige Turbine

Patentiert im Deutschen Reiche vom 22. September 1923 ab

Zur Vereinfachung und Verbilligung der Herstellung von Schaufeln ist es im Turbinenbau üblich, die gleiche Schaufelhöhe für mehrere Stufen von gleichem Beaufschlagungsdurchmesser zu verwenden. Handelt es sich um eine Gleichdruckbeschaufelung, bei der die einzelnen Räder nur teilweise, und zwar von Rad zu Rad zunehmend, beaufschlagt werden, so kann man Gruppen von Hochdruckstufen mit gleichen Schaufelhöhen ausführen. Auch für Überdruckturbinen, bei denen alle Stufen voll beaufschlagt werden, verwendet man, insbesondere im Hochdruckteil, Gruppen gleicher Schaufelhöhe bei gleichem Beaufschlagungsdurchmesser. Derartige Schaufelgruppen sind nun aber zur Erzielung eines guten Wirkungsgrades bei Dampfturbinen nicht geeignet, wie aus folgender Überlegung hervorgeht:

Wie bekannt, ist auf den Wirkungsgrad in erster Linie das Verhältnis der Dampf- zur Umfangsgeschwindigkeit von Einfluß, und zwar wird ein günstiger Wirkungsgrad bei einem bestimmten Wert dieses Verhältnisses erreicht, welches demnach für alle Stufen der Turbine vorliegen muß. Wählt man aber bei gleicher Schaufelhöhe gleichen Beaufschlagungsdurchmesser, also gleichen Durchgangsquerschnitt für die einzelnen Stufen, so nimmt die Dampfgeschwindigkeit infolge der Zunahme des spezifischen Volumens des Dampfes in jeder Stufe innerhalb der Gruppe aller Stufen die gleiche ist, so ist das Verhältnis der Dampf- zur Umfangsgeschwindigkeit bei den einzelnen Stufen einer Gruppe verschieden groß, und zwar steigt dieses Verhältnis von der ersten bis zur letzten Stufe jeder Gruppe mit der Dampfgeschwindigkeit an.

Die Erfindung will nun einen guten Wirkungsgrad bei einer mehrstufigen Turbine mit einer oder mehreren Gruppen gleicher Schaufelhöhe und zunehmenden Beaufschlagungsdurchmessern erreichen. Sie besteht darin, daß die Beaufschlagungsdurchmesser innerhalb jeder Gruppe genau oder nahezu mit der Quadratwurzel aus dem spezifischen Volumen des Treibmittels wachsen. Es sei hierzu bemerkt, daß eine kegelige Form der einzelnen Läufer von mehrstufigen Turbinen, also ein Wachsen der Schaufelkränze in Richtung des durchströmenden Dampfes, bekannt ist. Bei dieser Anordnung bleibt aber das Verhältnis von Dampf- zur Umfangsgeschwindigkeit nicht gleich. Ein gleichbleibendes Verhältnis jener Geschwindigkeiten und damit auch ein guter Wirkungsgrad ergeben sich erst bei einer Turbine nach der Erfindung, und zwar aus folgendem Grunde:

Zwei Stufen gleicher Schaufelhöhe mit den Beaufschlagungsdurchmessern d_1 und d_2, also den Umfangsgeschwindigkeiten u_1 und u_2, verarbeiten praktisch die gleiche Dampfmenge vom spezifischen Volumen v_1 und v_2.

Gegenlaufturbine mit vorwiegend axialer Beaufschlagung

Patentiert im Deutschen Reiche vom 24. Juni 1926 ab

Zur wirtschaftlichen Verarbeitung kleiner Dampfmengen in Dampfturbinen, insbesondere in den Hochdruckstufen, ist die Verwendung kleiner Beaufschlagungsdurchmesser erforderlich, damit die Schaufelhöhe einen kleinsten Wert nicht unterschreitet. Damit ferner die Stufenzahl nicht zu groß wird, erscheint die Verwendung von zwei im Gegensinne zueinander umlaufenden Wellen vorteilhaft.

Bisher ist es nur gelungen, zweckmäßige Bauarten einer Gegenlaufturbine mit radial beaufschlagten Stufen zu schaffen. Hier steigt aber der Beaufschlagungsdurchmesser von Stufe zu Stufe so stark, daß bei Zuführung hochgespannten Dampfes ungünstige Strömungsverhältnisse entstehen.

Gegenläufige Turbinen mit axialer Beaufschlagung sind zwar auch vorgeschlagen worden, haben aber nie praktische Bedeutung erlangt, weil die bisher bekannt gewordenen Vorschläge keine Grundlage für praktische Ausführungen abgeben können. Jedenfalls sind diese Vorschläge für hochgespannten Dampf völlig ungeeignet.

Die Erfindung ermöglicht eine praktisch brauchbare Bauart einer gegenläufigen Dampf- oder Gasturbine mit vorwiegend axialer Beaufschlagung. Sie besteht darin, daß die beiden Gegenläufer vorwiegend walzenförmig aufgebaut sind, wobei der eine Teil der walzenförmigen Körper zur Lagerung, der andere Teil zur Aufnahme der Beschaufelung dient und der Dampf durch eine Mittenbohrung mindestens einer Welle zugeführt wird. Durch die neue Anordnung wird erreicht, daß Dichtungen nur auf kleinem Durchmesser vorgenommen zu werden brauchen, und daß auch die Entlastung von Axialschüben nur auf kleinem Durchmesser zu erfolgen hat. Die Walzenform der Läufer ist besonders geeignet für höhere Drücke und hohe Drehzahlen, während bisher bekannt gewordene Vorschläge für Gegenlaufturbinen trommelförmige Schaufelträger enthalten, deren Durchmesser weit größer ist als der Durchmesser der Welle. Die sich hierdurch ergebenden ungünstigen Verhältnisse machen derartige Turbinenbauarten ungeeignet für hohe Drücke.

Abb. 1 stellt ein Ausführungsbeispiel dar, in welchem mit a der innere, mit b der äußere beaufschlagte Läuferteil bezeichnet wird.

Die Lagerung erfolgt bei d und d', die Fortleitung der mechanischen Arbeit durch die Zahnkränze e und e'. Der Dampfeintritt kann von einer oder von beiden Seiten durch die Rohre f und f' erfolgen. In den Läuferkörpern sind Rohre g und g' lediglich an den Wellenenden eingewalzt, so daß der Wärmeübergang aus dem beaufschlagten in den nicht beaufschlagten Teil jedes Läufers gering ist. Die Zwischenräume h und h' werden zu diesem Zweck mit Wärmeschutzmitteln gefüllt und gegebenenfalls auch luftleer gemacht. Die am Ende des inneren Läufers a untergebrachten Hochdruckstufen c sind in der Größe ihres Durchmessers nach innen nur durch die Größe der Dampfzuführungs-

Turbinenantrieb für Luftfahrzeuge

Patentiert im Deutschen Reiche vom 12. Oktober 1929 ab

Bei der Ausbildung des Antriebes von Luftfahrzeugen hat sich, vor allem bei der gleichzeitigen Anwendung einer größeren Zahl von Propellern, der Vorschlag bewährt, die einzelnen Propeller nicht nebeneinander, sondern paarweise hintereinander anzuordnen. Als Antriebsmaschinen können dabei entweder Verbrennungskraftmaschinen oder Dampfturbinen verwendet werden. Die vorliegende Erfindung befaßt sich mit der Ausbildung des Turbinenantriebes. Für diesen ist bereits früher vorgeschlagen worden, jedem Propeller seine eigene Antriebsmaschine zu geben, die unabhängig von der anderen arbeitet und unabhängig von dieser geregelt wird, oder die Antriebsmaschinen gegenläufig in einem Gehäuse zu vereinigen. Die Erfindung beschreitet zur Lösung der Aufgabe, einen Dampfturbinenantrieb für Luftfahrzeuge zu entwickeln, einen grundsätzlich anderen Weg. Die gleichachsige Anordnung der beiden Propeller wird beibehalten, aber die getrennten Maschinen werden durch eine einzige Maschine, nämlich eine Gegenlaufmaschine an sich bekannter Bauart, ersetzt, nämlich eine vielstufige axiale Gegenlaufturbine ohne Leitkanäle mit ineinandergesteckten Laufkränzen, und zwar in der Weise, daß jede der Wellen selbständig und unabhängig von der anderen unmittelbar oder über Geschwindigkeitsgetriebe je einen der beiden an den entgegengesetzten Enden des Maschinensatzes angebrachten Propeller antreibt. Der wesentliche Vorteil des Antriebes gemäß der Erfindung liegt darin, daß die Gegenlaufturbine axialer Bauart mit geringen radialen Abmessungen gebaut werden kann, also den Luftstrom des Propellers praktisch nicht stört, im Gegensatz zur radial beaufschlagten Gegenlaufturbine, bei der die vorteilhafte Ausnutzung des Dampfes nur unter entsprechender Vergrößerung des Durchmessers erzielt werden kann. Aus diesem Grunde ist die Gegenlaufturbine axialer Bauart besonders wertvoll für die bewährte Propelleranordnung, bestehend aus Zug- und Druckpropeller, die wiederum für die Turbine den Vorteil einer einfachen Wellenführung ergibt, da man die baulichen Schwierigkeiten der sonst erforderlichen ineinandergesteckten Propellerwellen vermeidet.

Die Turbine kann in eine Hochdruck- und eine Niederdruckturbine in getrennten Gehäusen unterteilt werden, wobei mindestens die Hochdruckturbine als Gegenlaufturbine ausgebildet ist. Hochdruck- und Niederdruckmaschine können auf besondere Propeller arbeiten oder ihre Leistung an gemeinschaftliche Propellerwellen abgeben.

In der Abb. 1 ist ein Ausführungsbeispiel für den unmittelbaren Propellerantrieb durch eine Gegenlaufturbine axialer Bauart dargestellt. Mit a ist die innere, mit b die äußere Welle bezeichnet. Die Dampfzuführung er-

ÖSTERREICHISCHES PATENTAMT.

PATENTSCHRIFT Nr. 112287.

KARL RÖDER IN HANNOVER.

Mehrstufige Dampf- oder Gasturbine.

Angemeldet am 5. Jänner 1928; Priorität der Anmeldung im Deutschen Reiche vom 5. Jänner 1927 beansprucht.
Beginn der Patentdauer: 15. Oktober 1928.

Die Verarbeitung des Hochdruckdampfes in Turbinen bietet Schwierigkeiten, insbesondere, wenn die Aufgabe gestellt ist, den Hochdruckdampf bis herunter zum Kondensationsdruck auszunutzen. Da der Hochdruckdampf mit relativ kleinen Beaufschlagungsdurchmessern und Dampfgeschwindigkeiten verarbeitet werden soll, so entsteht eine große Anzahl von Stufen, die in mehreren Gehäusen untergebracht werden müssen. Eine weitere Erhöhung des Wärmegefälles und damit auch der Stufenzahl ist notwendig, wenn man zur Vermeidung zu großer Dampfnässe innerhalb der Schaufelung Zwischenüberhitzung anwendet.

Anderseits ist mit Rücksicht auf die Betriebssicherheit und die Länge des Maschinenaggregates eine Vermehrung der Gehäusezahl der Turbinenanlage über drei hinaus kaum zulässig.

Die vorliegende Erfindung bezieht sich auf mehrstufige Dampf- oder Gasturbinen mit mindestens zwei Wellen in derselben Achse, zwischen deren Lagerstellen in an sich bekannter Weise Teile der Turbinen, der angetriebenen Maschinen oder der Verbindungsglieder angeordnet sind. Bei diesen Maschinen werden die erwähnten Schwierigkeiten dadurch überwunden, daß beide gegenläufig zu betreibenden Wellen über ihre benachbarten Lagerstellen hinaus derart verlängert sind, daß das eine Wellenende das andere umschließt und die beiden Enden in dem hiedurch gebildeten Zwischenraum axial beaufschlagte Schaufelkränze tragen.

In der Zeichnung veranschaulicht Fig. 1 schematisch ein Ausführungsbeispiel einer mehrstufigen Turbine gemäß der Anmeldung. Das hohl ausgebildete Ende der Welle a umschließt das innere Wellenende b im beschaufelten Teil und ist mit der Welle c eines Stromerzeugers d aus einem Stück hergestellt oder starr gekuppelt. Der die Schaufeln tragende Teil a bildet somit eine axiale, freitragende Fortsetzung der Stromerzeugerwelle c und übt auf diese insofern einen günstigen Einfluß aus, als er deren größte Durchbiegung verringert und damit gegebenenfalls die kritische Drehzahl des Stromerzeugers über die Betriebsdrehzahl verlegt, so daß die kritische Drehzahl beim Anfahren und Abstellen der Maschinen nicht durchfahren zu werden braucht.

Ähnlich wie der Läufer a kann auch der Läufer b in seinem beschaufelten Teil nur den Fortsatz einer in der Figur nicht gezeichneten Welle bilden, die als Träger weiterer Schaufelkränze dient und von einem Gehäuse umschlossen ist, dessen Abdampfstutzen g aus der Zeichnung noch erkennbar ist.

Der Hochdruckdampf wird der gegenläufigen Beschaufelung h zugeführt, u. zw. durch eine Bohrung der Welle b oder wie dargestellt, durch die Bohrung e der Stromerzeugerwelle c. An der Einführungsstelle des Dampfes ist eine Stopfbüchse f angeordnet, die derart ausgebildet wird, daß die vom Dampf am beaufschlagten andern Wellenende auf die Welle ausgeübten axialen Kräfte aufgehoben und von der Lagerung ferngehalten werden.

Die Welle b kann auch (wie a) als Fortsetzung einer Stromerzeugerwelle ausgebildet sein, wobei die beiden Stromerzeuger auf dasselbe Netz arbeiten, also elektrisch gekuppelt sind.

In Fig. 2 ist ein weiteres Ausführungsbeispiel dargestellt. Hier bedeuten wieder a und b den Hochdruckteil der mehrstufigen Turbine, deren Läufer durch die über das Lager m hinaus verlängerte Welle h in der Mitteldruckturbine q und durch die über das Lager n hinaus verlängerte Welle c der Niederdruckturbine r gebildet werden. Die Welle h ist außerdem bei o, die Welle c bei p gelagert. Zwischen den beiden Lagern m und o sind also die Laufkränze der Teilturbine q, zwischen den Lagern p und n die Laufkränze

Brennkraftturbine mit um die Welle liegenden Brennkammern

Patentiert im Deutschen Reiche vom 6. Dezember 1925 ab

Die Erfindung betrifft Brennkraftturbinen mit um die Welle liegenden Brennkammern, deren Ein- und Auslässe durch um die Laufradachse umlaufende Schieber geregelt werden.

Man hat bereits Turbinen vorgeschlagen, bei denen das Laufrad selbst als zylindrischer Drehschieber zur Regelung des Treibmittelaustrittes ausgebildet ist, und zwar derart, daß sich auf dem Umfange des Radkörpers Gruppen von Laufschaufeln und Steuerflächen abwechseln. Die Zahl der Gruppen wird hierbei von der Zahl der Brennkammern bestimmt. Der Gesamtwirkungsgrad solcher Anordnungen ist jedoch ein schlechter, einmal, weil eine große Zahl von Verbrennungen auf einen Umlauf des Laufrades kommt, sodann aber auch, weil bei einer großen Drehzahl und Umlaufgeschwindigkeit der Steuerflächen sich unzureichende und nicht überwachbare Verhältnisse bei der Füllung, Entspannung und Spülung ergeben. Dadurch ist die Erreichung höherer Geschwindigkeiten praktisch unmöglich.

Nun hat man weiter bereits von der Laufradachse untersetzt angetriebene und um diese umlaufende Drehschieber vorgesehen, um durch sie den Austritt der Gase zu regeln und durch eine Düse auf den im Inneren des Schiebers befindlichen Laufradkranz geleitet.

Durch die Erfindung sollen neue Vorteile erreicht werden. Sie besteht darin, daß die Steuerflächen durch einen besonderen, für Auslaßregelungen an sich bekannten, auf der Laufradachse der Turbine lose drehbaren Drehschieber, der untersetzt angetrieben wird, gebildet werden. Diese Anordnung beseitigt die Ventile an der Turbine völlig, insbesondere auch auf der Treibmitteleinlaßseite.

Ein weiterer Vorteil der Erfindung besteht darin, daß die Brennkammern nach außen gelegt sind, um so für das Gehäuse und den Drehschieber eine große Kühlfläche zu erhalten. Die Austrittsregelung der Gase aus den Kammern erfolgt erfindungsgemäß durch Gruppen von düsenförmigen Kanälen im Regelungsschlitz des Drehschiebers über einen Bereich zwischen den Austrittsöffnungen mindestens zweier benachbarter Brennkammern. Auf diese Weise wird dem Austritt der Gase ein größerer Zeitraum gelassen als bisher und gleichzeitig ihnen über die Gesamtdauer des Austrittes die gleiche Richtung gegeben.

Die in der Zeichnung dargestellte Ausführungsform stellt einen neuen Typ von Brennkraftturbinen dar, der insbesondere eine enge Bauart aufweist, die die Ausnutzung der Gase in mehreren Stufen gestattet. Die Anordnung der Innenverzahnung am Drehschieber bietet hierbei nicht unwesentliche bauliche Vorteile.

Bild 1 zeigt einen durch die Turbine mit Ausnahme der Übersetzungsräder gelegten Längsschnitt,

Bild 2 einen Querschnitt hierzu in der Richtung I zu I in Bild 1.

Die Brennkammern *a* sind am Umfange der Turbine angeordnet. Sie haben je eine äußere und eine innere zylindrische Begrenzungsfläche d_1 und d_2, in denen die Ein- und Austrittsöffnungen für den Betriebsstoff untergebracht sind. Äußere Ringkanäle *b* und *c* sind für die Zuführung von Gasgemisch und Spülluft vorgesehen. Der Drehschieber *d* besitzt in seinen zylindrischen Flächen d_1 und d_2 entsprechende Öffnungen *e* und *f* zur Regelung von Gemisch und Spülluft sowie düsenförmige Austrittsöffnungen *g* für die Gase, während die übrige Fläche jeweils die Brennkammern während der Verdichtungszeiten bis zur erfolgten Zündung geschlossen hält. *h* sind Labyrinthdichtungen, und *i* ist das Laufrad. Die Abgase werden im Raum *k* gesammelt und abgeführt. Zusammen mit dem Laufrad *i* ist auch ein Zahnrad *l* auf der Turbinenwelle *m* befestigt, das mit zwei Zwischenrädern *n* und *o* im Eingriff steht, von denen wenigstens *n* mit einer Achse *p* im Deckel *q* der Turbine fest gelagert ist. Dieser sowie der Gehäusedeckel *r* enthalten die Lager *s* der Welle *m*. *t* sind Zündkerzen.

Die anderen zum Betrieb der Turbine gehörigen Teile sind nicht mit eingezeichnet.

Im Ausführungsbeispiel sind sechs Brennkammern gezeichnet. Der Drehschieber ist symmetrisch mit zwei Gruppen von Ein- und Austrittsöffnungen für Gasgemisch und Spülluft und für gespannte Gase gezeichnet. Das Übersetzungsverhältnis betrage 6 : 1. Auf eine Umdrehung des Drehschiebers kommen demnach sechs Umläufe des Laufrades und zwölf Zündungen.

Bei einer größeren Zahl von Brennkammern kann man die Gruppeneinteilung noch weiter treiben, so daß beispielsweise bei 12 Kammern die 1, 4, 7, 10; 2, 5, 8, 11; 3, 6, 9, 12 gleichzeitig arbeiten.

PATENTANSPRÜCHE:

1. Brennkraftturbine mit um die Welle liegenden Brennkammern, deren Ein- und Auslässe durch um die Laufradachse umlaufende Steuerflächen geregelt werden, dadurch gekennzeichnet, daß die Steuerflächen durch einen besonderen, für Auslaßregelungen an sich bekannten, auf der Laufradachse lose drehbaren, untersetzt angetriebenen Drehschieber gebildet werden.

2. Brennkraftturbine nach Anspruch 1, dadurch gekennzeichnet, daß von den zwei konzentrischen Zylindersteuerflächen des Drehschiebers die äußere den Einlaß der außerhalb gelegenen Gas- und Luftzuleitungen nach den zwischen beiden gelegenen Brennkammern und die innere den Auslaß aus diesen nach den Laufradschaufeln überwacht und daß die Auslaßdüsen in dem inneren Zylinder den bis dahin von außen nach innen gerichteten Weg der Arbeitsmittel in einen axial oder nahezu axial gerichteten gegen die Laufradschaufeln umlenken.

3. Brennkraftturbine nach Anspruch 1, dadurch gekennzeichnet, daß der den Auslaß der gespannten Gase freigebende Regelungsschlitz sich über einen Bereich zwischen mindestens zwei benachbarten Brennkammeraustrittsöffnungen erstreckt und in diesem düsenförmige Kanäle (*g*) vorgesehen sind, die dem Betriebsmittel über die Gesamtdauer des Austritts die gleiche Richtung geben.

4. Brennkraftturbine nach Anspruch 1 und 2, gekennzeichnet durch eine Innenverzahnung am Drehschieber.

Brennkraftturbine mit umlaufenden, auf einem Radkranz angeordneten Brennkammern

Patentiert im Deutschen Reiche vom 18. September 1925 ab

Gegenstand der Erfindung ist eine Brennkraftturbine mit umlaufenden, auf einem Radkranz angeordneten Brennkammern. Die bekannten Brennkraftturbinen dieser Art sind so beschaffen, daß die Beschickung und Entlüftung der Brennkammern sowie die Abströmung der Verbrennungsgase seitlich, also in axialer Richtung, und die Zündung des Gasgemisches gleichzeitig mit dem Abströmen in die Leitschaufeln erfolgen. Hieraus ergeben sich verschiedene Nachteile, welche die Bedienung der Maschine erschweren und deren Wirkungsgrad vermindern. Die seitliche Beschickung erfordert zwangläufig den Einbau der Steuerungsorgane, Ventile und Zündeinrichtungen im Innern der Maschine, so daß sie schwer zugänglich sind und Betriebsstörungen beim unregelmäßigen Arbeiten dieser Organe nur durch schwierige und zeitraubende Arbeiten behoben werden können. Das mit der Zündung gleichzeitig abströmende Gasgemisch verbrennt nicht gleichmäßig und unvollständig, wodurch sich ein uneinheitlicher, die Leistung der Turbine herabsetzender Verpuffungsdruck ergibt.

Mit der Erfindung wird die Beseitigung dieser Nachteile bezweckt. Die neue Erfindung besteht darin, daß die Beschickung und Entlüftung der Brennkammern radial von außen, die Abströmung der Verbrennungsgase dagegen beiderseits des Triebrades axial erfolgt, wobei die das Triebrad seitlich einschließenden Leitschaufelauslässe hinter der zugehörigen Zündstelle ansetzen.

Der Einbau der Zündmittel, Ventile und Steuerorgane in Radialkanälen ist einfach durchzuführen, ebenso lassen sich diese Organe leicht überwachen, regeln, instand halten und instand setzen, wodurch der Betrieb wesentlich gefördert wird. Die Zurücksetzung der Leitschaufelauslässe führt zur gleichmäßigen und vollständigen Verbrennung des Gemisches, so daß sich der Druck der Verbrennungsgase jeder Brennkammer zu einem gleichmäßigen Verpuffungsdruck ausgleichen kann.

Auf der Zeichnung ist eine Brennkraftturbine nach der Erfindung in einer Ausführungsform beispielsweise in Abb. 1 im Querschnitt und in Abb. 2 im Höhenschnitt dargestellt. Abb. 3 zeigt die Anordnung von einzelnen Teilen der Turbine.

Hierbei ist 1 das in der Mitte der Turbine befindliche, von der hohlen Welle 9 mitgenommene Triebrad, welches in seinem Kranz in bekannter Weise eine Anzahl, z. B. fünf, Brennkammern 2 enthält, welche gegen das Gehäuse 3 bei 4 abgedichtet sind. Aus jeder Brennkammer führen winklig zur Achse liegende Düsen 5 in die Seitenwände des Triebrades 1. Dieses ist durch eine Mittelwand 6 geteilt, welche nahe ihrem Rande Durchlässe 7 besitzt. Beide Triebradhälften stehen mittels Bohrungen 8 mit der Hohlwelle 9 zwecks Erzielung einer Umlaufkühlung in Verbindung. Beiderseits des Triebrades sitzen auf der Welle 9 ein oder mehrere am Umfange mit Schaufeln 11 besetzte Laufräder 10.

Zwischen dem Triebrad 1 und den sich anschließenden Laufrädern 10 und, wenn mehrere der letzteren vorhanden sind, auch zwischen je zwei benachbarten Laufrädern sind an ringförmigen Zwischenwänden des Gehäuses Leitschaufeln 12 vorgesehen, welche, entsprechend der Aufeinanderfolge der Verbrennungsvorgänge, nur auf einem Teil des Umfangs ihrer Träger, also absatzweise, angeordnet sind. Im Gehäuse vorgesehene Ringkanäle 13 dienen zur Ableitung der Abgase; der Gehäusemantel 14 bildet einen Teil der Kühlung.

Gemäß der Erfindung sind nun die zum Betriebe der Turbine erforderlichen, vom Triebrad 1 gesteuerten Kanalsätze, und zwar Brennstoffeinlaß 15, Zündkanal 16 und Entlüftungskanal 17, radial im Gehäuse angeordnet. Wie aus Abb. 2 ersichtlich, sind bei der gewählten Ausführungsform drei solcher Kanalsätze vorgesehen.

Die Leitschaufeln 12 setzen erfindungsgemäß etwas hinter dem zugehörigen Zündkanal 16 an und enden in der Nähe des Entlüftungskanals 17.

Die Wirkungsweise der Turbine ist folgende: Die jeweils dem Brennstoffeinlaß 15 gegenüberliegende Brennkammer 2 wird radial von außen mit dem flüssigen oder gasförmigen Brennstoff beschickt, wozu sowohl ein gesteuertes Einlaßventil als auch ein Einlaßschlitz in Verbindung mit einem unter Druck stehenden Brennstoffgemischbehälter Verwendung finden kann.

Nach dem Anwerfen der Turbine kommt die beschickte Brennkammer 2 zum Zündkanal 16 mit Zündkerze oder Glührohr, wodurch sich das Gasgemisch entzündet, ohne jedoch sofort abströmen zu können, da die Leitschaufeln 12 erst hinter der Zündstelle 16 ansetzen. Dadurch ergibt sich einerseits eine Reihenzündung und andererseits eine Ausgleichung des Verpuffungsdrucks der Verbrennungsgase, welche dann gleichförmig und vollständig verbrannt seitlich, also axial zu den Leitschaufeln 12, abströmen und die Turbine in Bewegung halten. Die beschickte Brennkammer kommt sodann in den Bereich des Entlüftungskanals 17 und wird, z. B. mittels eines Schleudergebläses, radial entlüftet, welches auch die Leitschaufeln 12 und Laufradschaufeln 11 entlüftet und kühlt. Die neuerliche Beschickung der entleerten Brennkammern erfolgt erst dann wieder, wenn die Düse 5 gegen die Leitschaufeln 12 abgeschlossen ist.

Die Taktvorgänge spielen sich dabei in der Weise ab, daß die Zündungen nach Maßgabe der Brennkammernstellung gegenüber den Zündkanälen erfolgen.

PATENTANSPRUCH:

Brennkraftturbine mit umlaufenden, auf einem Radkranz angeordneten Brennkammern, dadurch gekennzeichnet, daß die Beschickung und Entlüftung der Brennkammern (2) radial von außen und die Abströmung der Verbrennungsgase beiderseits des Triebrades (1) axial erfolgt, wobei die das Triebrad seitlich einschließenden Leitschaufelauslässe (12) zur Erzielung einer gleichförmigen und vollständigen Verbrennung des Gemisches hinter der zugehörigen Zündstelle (16) ansetzen, so daß sich der Druck der Verbrennungsgase jeder Kammer (2) vor dem Abströmen durch die Leitschaufelauslässe (12) zu einem gleichmäßigen Verpuffungsdruck ausgleichen kann.

Hermann Oberth in Mediasch-Medias, Rumänien.

Brennkraftturbine mit Hilfsflüssigkeit.

Patentiert im Deutschen Reiche vom 19. Februar 1925 ab.

Bei bekannten Brennkraftturbinen, bei welchen eine in einem Zylinder gestaute Flüssigkeit durch die Verbrennungsgase auf eine Turbine geeigneter Bauart getrieben wird, wird die ganze innere Zylinderoberfläche durch die Flüssigkeit benetzt und abgekühlt. Infolgedessen verliert das Gas bereits anfangs viel Wärme, was bei der hohen Anfangstemperatur einen bedeutenden Energieverlust und eine wesentliche Verschlechterung des Wirkungsgrades zur Folge hat. Wollte man die Kühlung und Benetzung des oberen Zylinders dadurch verhüten, daß man den Zylinder nur teilweise mit Flüssigkeit füllt, so entstünde ein großer schädlicher Raum, der ebenfalls den Wirkungsgrad der Maschine herabsetzen würde.

Die Erfindung will diesen Nachteil vermeiden. Sie besteht darin, daß die Flüssigkeitssäule einen Stempel trägt, welcher eine Füllung des Arbeitszylinders mit Flüssigkeit ohne Bildung eines schädlichen Raumes gestattet. Der Stempel ist mit einem Schwimmkörper fest verbunden, welcher in der oberen Totpunktlage das Einströmen von Flüssigkeit in den darüberliegenden Zylinderraum, in der unteren Totpunktlage den Ablauf der Flüssigkeit verhindert und den Stempel unmittelbar auf der Oberfläche der Flüssigkeitssäule hält. Die abdichtenden Teile des Schwimmkörpers sind zweckmäßig aus elastischem Stoff. Stempel und Schwimmkörper sind durch eine Führungsstange im Zylinder so geführt, daß sie die Zylinderwandungen nicht berühren. Die Führungsstange ist nach unten verlängert und trägt einen Schieber, welcher in der oberen Totpunktstellung die Flüssigkeitszufuhr schwächt oder ganz absperrt.

Die Zeichnung zeigt eine Ausführungsform der Erfindung, und zwar

Abb. 1 den Zylinder im Schnitt bei oberer Totpunktstellung des Stempels,

Abb. 2 desgleichen bei unterer Totpunktstellung des Stempels,

Abb. 3 einen Schnitt nach Linie *A-B* zu Abb. 1,

Abb. 4 einen Schnitt nach Linie *C-D* zu Abb. 2.

Durch die im Zylinder *a* gestaute Flüssigkeitssäule (Abb. 1), deren Spiegel durch strichpunktierte Linien angedeutet ist, wird ein Stempel *b* getragen, dessen Form der des Zylinders angepaßt und dessen Querschnitt etwas kleiner als der des Zylinders ist. Stempel *b* ist durch eine Stange *c* mit einem Schwimmkörper *d* fest verbunden, welcher in der in Abb. 1 gezeichneten Stellung mit seiner oben abgeschrägten und zweckmäßig mit Gummi belegten Kante gegen einen in den Zylinderquerschnitt ragenden Ring *e* anliegt und so das Einströmen von Flüssigkeit in den darüberliegenden Zylinderraum verhindert. Auf diese Weise ist erreicht, daß der Flüssigkeitsspiegel die durch die strichpunktierten Linien angedeutete Grenze niemals überschreiten kann. Führungsstange *c* ist nach unten verlängert und trägt einen Schieber *f* in Form eines Hohlzylinders, welcher in der oberen Totpunktstellung die Mündung des Zuleitungsrohres *g* der Flüssigkeit ganz oder teilweise abschließt. In seiner unteren Totpunktstellung (Abb. 2) schließt der Schwimmkörper *d* den Abfluß der Flüssigkeit, so daß das in dieser Abbildung ebenfalls strichpunktiert angedeutete Niveau der Flüssigkeitssäule diese Grenze nach unten nicht überschreiten kann. Die nach unten abdichtenden Flächen des Schwimmkörpers *d* sind aus geeignetem elastischen Stoff *h* zum Zweck, den Stoß aufzufangen. Die Stange *c* ist an zwei Stellen geführt (Abb. 3 und 4), so daß weder der Stempel noch der Schwimmkörper die Zylinderwandungen berührt. Hierdurch wird die Innenauskleidung des Zylinders geschont und Reibungsarbeit vermieden.

Die Arbeitsweise der in den Abb. 1 und 2 dargestellten Vorrichtung ist folgende:

Durch das Wasserzuleitungsrohr *g* wird Wasser in den Arbeitszylinder eingelassen, so lange, bis Stempel *b* seine oberste Stellung erreicht hat und Schwimmkörper *d* gegen Ring *e* anliegt. Gleichzeitig wird die Wasserzuleitung durch Schieber *f* abgeschwächt oder ganz gesperrt und mittels des bisher geschlossenen Dreiweghahnes *i* die Gaszufuhr freigegeben. Unter dem Einfluß des expandierenden Gases wird die in dem Zylinder gestaute Flüssigkeitssäule durch ein Rohr *k* der Turbine zugeführt. Durch Umstellen des Hahnes *i* wird anschließend die Auspufföffnung freigegeben, so daß durch die erneut in den Zylinder einströmende Flüssigkeit Schwimmer *d* und Stempel *b* wieder hochgehoben und die Verbrennungsgase ausgepufft werden.

PATENT-ANSPRÜCHE:

1. Brennkraftturbine, bei welcher die Verbrennungsgase eine Hilfsflüssigkeit aus einem Behälter auf eine Turbine treiben, dadurch gekennzeichnet, daß die Flüssigkeit einen Stempel (*b*) trägt, welcher eine Füllung des Arbeitszylinders (*a*) mit Flüssigkeit ohne Bildung eines schädlichen Raumes gestattet.
2. Turbine nach Anspruch 1, dadurch gekennzeichnet, daß der Stempel (*b*) mit einem Schwimmkörper (*d*) fest verbunden ist, welcher in der oberen Totpunktlage das Einströmen von Flüssigkeit in den darüberliegenden Zylinderraum, in der unteren Totpunktlage den Ablauf von Flüssigkeit verhindert und den Stempel unmittelbar auf der Oberfläche der Flüssigkeitssäule hält.
3. Turbine nach Anspruch 1 und 2, dadurch gekennzeichnet, daß die abdichtenden Teile des Schwimmkörpers aus elastischem Stoff bestehen.
4. Turbine nach Anspruch 1 bis 3, dadurch gekennzeichnet, daß Stempel und Schwimmkörper durch eine Führungsstange (*c*) im Zylinder (*a*) geführt sind, so daß sie die Zylinderwandungen nicht berühren.
5. Turbine nach Anspruch 1 bis 4, dadurch gekennzeichnet, daß die Führungsstange einen Schieber (*f*) trägt, welcher in der oberen Totpunktstellung die Flüssigkeitszuführung absperrt.

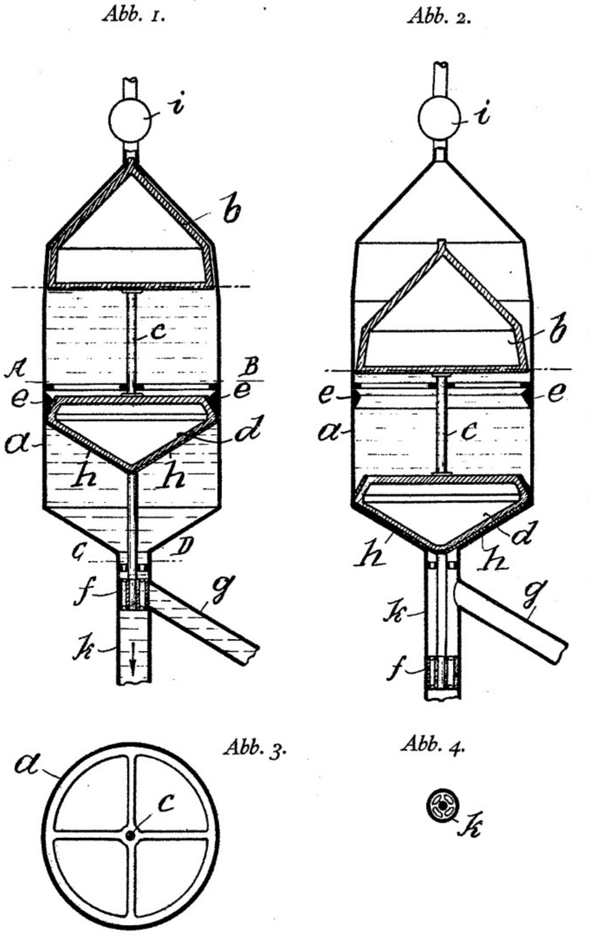

Figure 9.64: Hermann Oberth filed a patent application on gas turbine engines for aircraft in 1925.

One of the most important figures in the development of jet technology was Hans von Ohain (German, 1911–1998), a young physicist who dreamed of creating practical jet engines and aircraft. Working with the mechanic Max Hahn (German, 18??–19??), von Ohain designed his first prototype jet engine in 1933 and demonstrated it in 1935 (Fig. 9.65, top). Von Ohain's biographer Margaret Conner described the prototype [Conner 2001, pp. 38–39]:

> Von Ohain said that in a little storage room behind the shop, "We made a little model according to my own sketches. It was about three feet in diameter and about one foot wide. The blades were made of heavy sheet metal. Almost nothing was welded because Hahn was more a man for clean machining operations, and for fastening with bolts and nuts." It was a pancake engine for either vertical or horizontal thrust, a very light design. [...]
>
> Von Ohain moved his device to the back room of the Bartels and Becker garage. It was exciting to von Ohain and Hahn if the device worked at all. Each time the model was tested, long yellow flames streaked out. [...] Max Hahn, normally very stern and skeptical, seemed in this instance to be quite positive and optimistic. He conceded, in a rare glimpse of a sense of humor, "At least the flames came out of the right place," and with high velocity. The engine did not self-sustain but did result in the unloading of the starter [doing the work of the starter motor when burning]. Instead of the pounding of the conventional engine there was a smooth flow of power, and a new sound, a piercing whistle.

The 1935 prototype jet engine of von Ohain and Hahn caught the attention of Ernst Heinkel (German, 1888–1958), a politically very powerful aircraft manufacturer who hired them in 1936 and provided them with all the resources and long-term support needed to build and test improved versions such as the HeS 1 (Fig. 9.65, bottom) [Conner 2001, pp. 61–62]:

> The project engine was designated the He S 1, He S for *Heinkel-Strahltriebwerk* (Heinkel jet engine). The He S 1 engine was made essentially of sheet steel fabricated at the Marienehe works and disks created at a nearby shipyard. It consisted of a back-to-back radial compressor and a radial inflow turbine. The rotor diameter was 12 inches (300 mm). The demonstrator combustor did not present any significant problems. The engine operated at a speed of 10,000 rpm and produced a thrust of 250 lbs (1.1 kN). It performed flawlessly under design conditions and during transient acceleration and deceleration. The sound was smoothed and focused, and the size of the unit was suitable for an aircraft. [...]
>
> The He S 1 engine was completed and installed in the test bed about the end of February 1937. Von Ohain said that the first test took place in March 1937.

A further improved engine, the HeS 3 (Figs. 9.66– 9.67), was first run in March 1938. It was then installed in a Heinkel He 178 aircraft, which in August 1939 became the world's first operational jet plane. Sterling Pavelec, professor of aerospace history at the USAF Air Command and Staff College, described the first test flight [Pavelec 2007, p. 22]:

> On August 27, 1939, Heinkel test pilot Erich Warsitz lifted off the airfield at Marienehe completing the first ever jet flight. The Heinkel team had ushered in a new era of aeronautical engineering. [...]
>
> The HeS 3b turbojet that powered the Günther's He 178 V1 produced 500 kg (1,100 lbs) thrust. The plane was designed around the engine, with the air intake in the nose and a tubular frame that housed the centrifugal-flow engine. Warsitz took off for the first time in a turbojet-powered aircraft and achieved a top speed—with the wheels down—of 300 kmph (187 mph). Warsitz was also the first to suffer a jet bird strike, which cut his flight short, but without substantial damage to the airplane or engine.

That initial single-engine jet aircraft was followed by the twin-engine He 280 jet aircraft in early 1941, using the newest HeS 8 engines (Fig. 9.68, first run September 1940) [Pavelec 2007, p. 28]:

> The He 280 airframe was prepared, and the anticipated HeS 8a engines were finally ready by March 1941. [...] The first engines were delivered, the plane was readied, and the chief test pilot Fritz Schäfer was able to make the first flight in the twin-engine He 280 on March 30, 1941. The plane tested well[....]

Von Ohain and his collaborators such as Max Hahn and Wilhelm Gundermann (German, 1904–1997) developed a long series of ever-improving jet engines in the 1930s and 1940s. Figure 9.69 shows Heinkel and von Ohain celebrating the flight of the He 178 in 1939; it also shows von Ohain's last known completed wartime engine, the He S 011, which he developed with Max Adolf Müller (German, 1901–1962) in 1943.

In addition to the He 178 and the twin-engine He 280 jet fighter, Heinkel's wartime team developed He 162 jet fighters (p. 1699) and apparently even intercontinental jet bombers (Section E.1).

After the war, von Ohain helped develop a wide range of jet and rocket engines in the United States.

AIRCRAFT POWER PLANT

Max Hahn, Seestadt Rostock, Germany, assignor
to Ernst Heinkel, Warnemunde, Germany

Application May 31, 1939, Serial No. 276,572
In Germany May 27, 1938

6 Claims. (Cl. 60—35.6)

The invention relates to a power plant, especially a propulsion unit of aircraft, due to the reaction or rocket effect, with an air compressor, a combustion plant and a gas turbine driving the compressor.

Object of the invention is to provide a driving apparatus of little weight, which is compact and in which difficulties for journalling are avoided.

A further object of the invention is to provide an apparatus which is especially adapted for fast aircraft.

A further object of the invention is to reduce the frontal face of the apparatus and thereby its resistance against the flow of air by a suitable location of the combustion chamber. This feature is of great importance for manufacturing very fast aircraft.

A further object of the invention is to branch part of the air compressed by the compressor and to mix this branched air with the combustion gases of high temperature leaving the combustion chamber and thereby obtaining a low temperature at the entrance of the turbine, a good efficiency of the combustion in the combustion chamber being maintained.

A further object of the invention is to form parts of the combustion chamber detachable for the access to the interior of the combustion chamber, especially to the nozzles of the burners to interchange them.

Further features of the invention will be given in the following description and the drawings.

Fig. 1 is a longitudinal section of the apparatus, and

Fig. 2 is a vertical section according to the line II—II of Fig. 1.

Referring to the drawings, 1 designates the blower, 2 the combustion chamber and 3 the turbine. The blower 1 and the turbine 3 are encased in a common housing 4, provided with an inlet aperture 5 and an outlet aperture 6. The blower 1 and the turbine 3 are arranged upon a shaft 7, rotatably mounted in bearings 7′. The bearings 7′ are in turn supported by brackets 8, 8 which are attached to the housing 4 in the inlet aperture 5 and the outlet aperture 6. The blower 1 and the turbine 3 are not arranged directly upon the shaft 7, but upon a tube 9 held at some distance from but firmly connected to the shaft 7. Both the blower 1 and the turbine 3 possess a plurality of vanes 10, 11 arranged radially upon the tube 9, said vanes being separated from one another by a partition wall 12 attached to the tube 9, so as to form a plurality of chambers constituting U-shaped guides for the flow medium. Both at the inlet aperture of the blower as well as at the outlet aperture of the turbine the vanes 10 and 11 are bent off at 13. At the outlet aperture 6 is provided a flow element 21 which is intended to prevent the formation of eddies.

The housing 4 encasing the blower 1 and the turbine 3 carries at its front end the annular combustion chamber 2, a substantial portion of which, in the example illustrated, is constituted by a simple shell 14 which is flanged on to the housing 4 and in which fuel inlets 15 are arranged. Within the combustion chamber 2, a guide vane 16 spaced from the front portion of the housing 4 is also provided, said guide vane being adapted to guide a portion of the air conveyed by the blower as combustion air into the combustion chamber 2 and thence to the intermediate mixing chamber 17.

The guide vane 16 overlaps in a certain distance the radial outlet aperture of the compressor and is furnished at its inside with an annular air scoop with triangular cross section; that part is indicated by the reference number 22.

Spaced from the shell 14 which constitutes the outer wall of the combustion chamber 2, a further dish-shaped guide vane 18 is provided which, together with the guide vane 16, forms an annular channel 19 leading out of the combustion chamber 2. The distance between the guide vane 18 and the shell 14 is in this case smaller than the distance between the guide vane 16 and the front portion of the housing 4. The dish-shaped guide vanes 16 and 19 consist preferably of thin sheet metal having high heat-resistance whilst the remaining parts of the apparatus insofar as they are exposed to stresses, preferably consist of high-quality steel. Within the combustion chamber 2 numerous burners 20 conveniently distributed uniformly over the entire periphery of the combustion chamber 2 are provided. At the outlet end of the apparatus a flow element 21 of stream-lined form is provided.

The apparatus of the invention operates as follows:

The fuel, e. g. gasoline, is ignited at 20 by the burners distributed over the entire periphery of the combustion chamber 2. The blower 1 and turbine 2 are started in suitable manner familiar to the man skilled in the art, e. g. by means of compressed air. When the blower and the turbine are rotating, air is sucked by the blower 1 through the entrance opening 5 in an axial direction and this air is compressed. The compressed air is discharged in a radial direction from the outlets of the blower 1 into the intermediate mixing chamber 17. A portion of the compressed air is fed into the branch line terminating at the periphery of the blower 1 and this air is led through the passage formed by the guide vanes 16 and part of the walls of the housing 4. A portion of this branched air is discharged into the combustion chamber 2 and serves for completely burning the fuel fed by the fuel inlets 15. The rest part of the branched air flows between the walls 14 and 18 and is fed back to the intermediate mixing chamber 17. The hot combustion gases produced in the combustion chamber 2 leave the combustion chamber 2 through the ring channel 19 into the intermediate mixing chamber 17; in this chamber they are partly mixed with the colder air streams surrounding this hot stream inwardly and outwardly in the intermediate mixing chamber 17. Then this mixture of combustion gases and compressed air flows into the inlet openings of the radial turbine 3 and part of the energy of the gases and compressed air is absorbed in this turbine. Then the gases leave the radial turbine in an axial direction through the outlet end 6 of the apparatus.

The portion of the cold air conveyed by the blower 1 and guided by the guide vane 16 towards the front side of the apparatus cools both the portion of the housing wall which is located within the combustion chamber 2 as well as the dish-shaped external wall 14 of the combustion chamber 2 and the dish-shaped guide vanes 16 and 18.

The cold air conveyed by the blower 1 into the mixing chamber 17 is there driven outwardly owing to its gravity. Due to the fact that the hot gas of the combustion chamber entering through the passage 19 into the intermediate mixing chamber is forced through the cold air in the intermediate mixing chamber 17 a very intensive mixing of the cold air and hot gas is effected, special mixing devices not being necessary. The resultant mixture of air and combustion gases drives the turbine 3 and after passing through the turbine 3 leaves the apparatus with a certain content of energy, such that it produces a reaction force.

The energy which, by means of the blower is imparted to the flowing medium, e. g. the air which flows in, is increased by the amount of energy of the fuel introduced, so that a considerably increased energy is available for driving the turbine and for generating a reaction force.

What I claim is:

1. In an aircraft power plant operating by the effect of reaction, a housing, a channel in the housing for introducing air and a channel for discharging gas, a bearing connected to the housing and disposed in the entrance channel, another bearing connected to the housing and disposed in the discharge channel, a rotor journalled in the bearings and comprising a one-step compressor and a one-step turbine, entrance openings being provided in the compressor adjacent to the entrance channel of the housing and discharge openings being provided in the turbine adjacent to the discharge channel of said housing, said compressor having outlet ports and said turbine having inlet ports the compressor also having vanes arranged in meridian sections and simultaneously arranged axially for introducing the air and radially for the discharge of the air, the turbine likewise having vanes arranged in meridian sections and simultaneously arranged radially for the introduction of the gas and axially for the discharge of the gas and a ring-shaped combustion chamber connecting the outlet port of the compressor and the inlet port of the turbine, the said combustion chamber being arranged at the frontal surface of the housing coaxially around the entrance channel for the air.

2. An aircraft power plant according to claim 1, in which the ring-shaped combustion chamber consists of a pressure-tight housing and heat resistant inner walls, which form an air-channel between the housing and the combustion chamber.

3. An aircraft power plant according to claim 1, in which the ring-shaped combustion chamber consists of a pressure-tight housing and heat resistant inner walls, said walls forming an air-channel between the housing and the combustion chamber, said air channel having a ring shaped discharging opening arranged on the inner diameter of the combustion chamber and serving for discharging combustion air into the said combustion chamber.

4. An aircraft power plant according to claim 1, in which the ring-shaped combustion chamber consists of a pressure-tight housing and heat resistant inner walls, which form an air-channel between the housing and the combustion chamber, part of the wall overlapping the discharge opening of the compressor and having means for branching off a portion of the air emerging from the compressor.

5. An aircraft power plant according to claim 1, in which the ring-shaped combustion chamber consists at least of two stationary parts, one of which forms a front part and is detachable.

6. An aircraft power plant according to claim 1, in which the ring-shaped combustion chamber consists of a pressure-tight housing and heat resistant inner walls, which form an air channel between the housing and the combustion chamber, part of the wall over-lapping the discharge opening of the compressor and having means for branching off part of the air emerging from the compressor, said air channel having a ring-shaped discharging opening arranged on the inner diameter of the combustion chamber for discharging combustion air in the combustion chamber, and said combustion chamber consisting at least of two stationary parts, one of which forms a front part and is detachable.

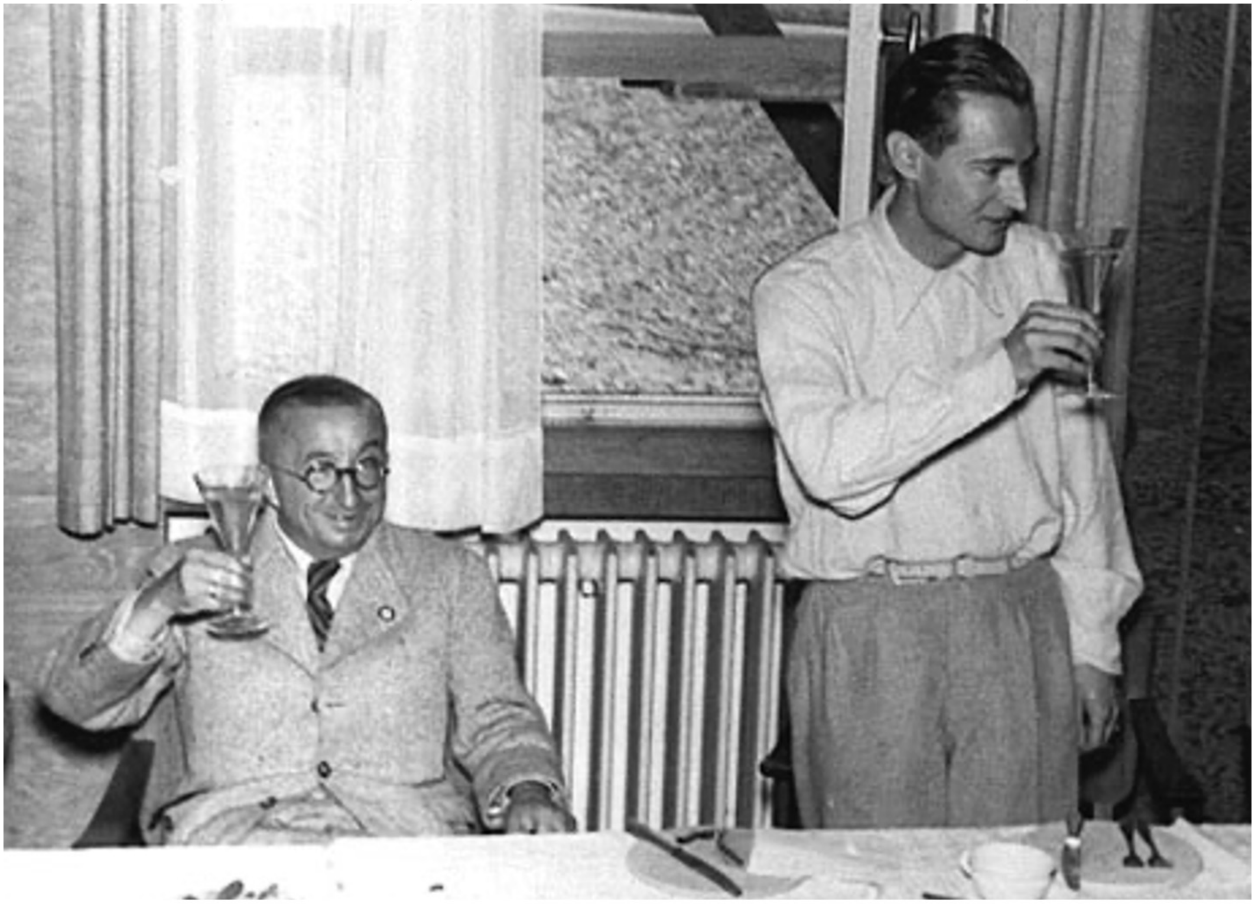
Hans von Ohain
(1911–1998)



Ohain-Müller HeS 011 turbojet engine (first run September 1943)

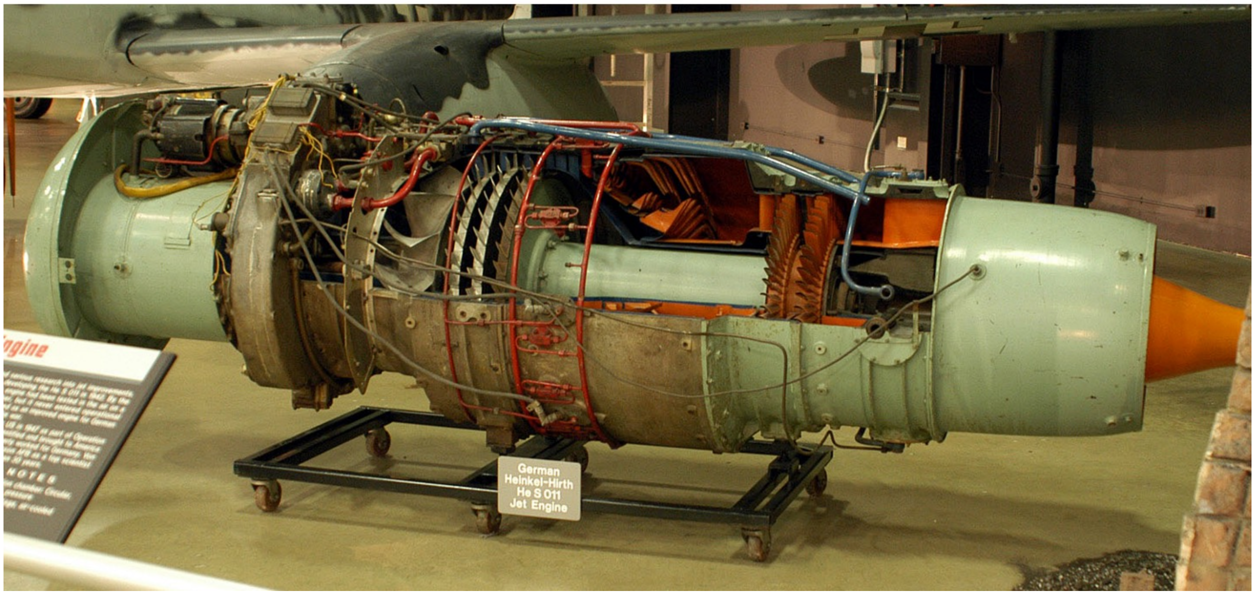


Figure 9.69: Top: Ernst Heinkel and Hans von Ohain celebrating the flight of the first jet aircraft, the Heinkel He 178, in 1939. Bottom: The HeS 011 turbojet engine, developed by von Ohain and Max Adolf Müller (first run September 1943).

Albert Betz (German, 1885–1968) and Walter Encke (German, 1888–1982), shown in Fig. 9.70, developed axial-flow compressors, which were utilized in most wartime German jet engines and virtually all modern jet engines. Betz also developed highly efficient wind turbine designs that are now used worldwide (p. 1665).

Herbert Wagner (Austrian, 1900–1982) and Max Adolf Müller (German, 1901–1962) led a team that was working to develop axial-flow compressors and prototype turbojet, turbofan, and turboprop engines at Junkers in the 1930s, as shown in Figs. 9.71–9.75. Due to management difficulties at Junkers, in 1939 Wagner left Junkers to create guided missiles and smart bombs at Henschel (see Section 9.6). Müller and most of the rest of Wagner's jet engine team (such as Rudolf Friedrich, German, 1909–1998) joined von Ohain's jet engine development program at Heinkel. Wagner also worked on German nuclear weapons programs during the war (p. 4165). After the war, Wagner developed a wide range of guided missiles and smart bombs in the United States, and Müller designed jet engines and related technologies in the United Kingdom.

After Wagner and Müller left the Junkers company, Anselm Franz (Austrian, 1900–1994) quickly rebuilt the jet engine program and engineering team at Junkers in 1939. Franz and his team designed and demonstrated the Jumo (Junkers Motors) 004 axial-flow turbojet engine (first run in 1940, Fig. 9.76); at least 8000 Jumo 004 engines were produced during the war. Franz and his team also developed other engines such as the Jumo 022 turboprop engine (Fig. 9.84).

After the war, Anselm Franz moved to the United States and joined the Lycoming company, along with many members of his Junkers jet engine team, including Heinrich Adenstedt (German, 1910–1991), Hans Berkner (German, 19??–19??), Friedrick Bielitz (German, 19??–19??), Siegfried Decher (German, 19??–19??), Heinz Moellmann (German, 19??–19??), and Wolfgang Stein (German, 19??–19??). At Lycoming, they produced the T53 and T55 turboshaft engines (which became widely used in helicopters and turboprop planes), PLF1 turbofan engine (the first high-bipass turbofan engine, important for jet airliners), AGT1500 turboshaft engine (for tanks and other land and sea vehicles, as well as stationary power plants, p. 1381), and other jet and gas turbine engines (pp. 1740–1743).

Early turbojet engines were challenged by overheating of the central components, especially the turbine blades, which shortened the operational lifetime of an engine before it needed to be rebuilt or replaced. That challenge arose both because of the extremely high temperatures achieved inside the engines and also because of the shortage of major high-temperature metals due to Allied blockades and bombing. In response, engineers such as Hermann Hagen (German, 19??–19??), Karl Leist (for his DB 007 engine), Paul Leistritz (German, 18??–1957), and Christian Lorenzen (German, 19??–19??) developed methods of directly cooling the blades inside a turbine. Many other scientists and engineers developed novel high-temperature ceramics (p. 667) and new high-temperature metal alloys (p. 689) that could be fabricated into turbine blades. For example, both in Germany during the war and in the United States after the war, Anselm Franz collaborated very closely with Heinrich Adenstedt (German, 1910–1991, pp. 697–698), an expert on high-temperature metal alloys. Such high-temperature ceramics and alloys are still widely used in a variety of modern engine types.

COMPLETE SPECIFICATION

An Improved Method of and Means for Propelling Aircraft

I, Prof. Dr. HERBERT WAGNER, a German citizen, of Cunostrasse 67b, Schmargendorf, Berlin, Germany, do hereby declare the nature of this invention, and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

In order in the case of combustion engines of the piston type, which are employed, for example, for driving the airscrews of aircraft, to maintain the output substantially constant at high altitudes despite the decreased density of the air at these heights it is usual to provide compressors which supply compressed air to the engine.

It has also been proposed to provide between the engine and the propeller a gear having a variable transmission. This gear has the object of varying the circumferential velocity of the airscrew as compared with the substantially constant velocity of the engine, in order to be able to adapt the running conditions of the airscrew to the different altitudes concerned. These variable speed gears have not been adopted in practice owing to the fact that the variable airscrew (airscrew having a variable pitch), which was introduced in the meantime, largely eliminated any necessity for varying the speed of the airscrew.

There have also been proposed for the propulsion of aircraft gas turbines comprising in substance a compressor, a combustion chamber, and a turbine driven by the burnt gases. It is known to employ these turbines as reaction or " rocket " device, in which case they eject the combustion gases towards the rear, or for driving the conventional type of propeller.

In order to maintain the output of these gas turbines substantially constant at different altitudes it has also been proposed, in adaptation to the practice adopted in respect of internal combustion engines, to furnish special compressors for supplying the turbine with compressed air, so that the circumferential velocity of the turbine will remain substantially the same irrespective of the particular height.

The provision of these compressors is accompanied by the disadvantage of considerably increased weight and a much more complicated design of the entire power aggregate.

The invention provides a new method of diminishing, or entirely eliminating, a drop in output at comparatively high altitudes in the case of gas turbines. According to the invention, the circumferential velocity of the gas turbine is increased with increasing altitude. In this way there is obtained in face of the existing art a considerably simplified construction. There may be obtained at higher altitudes a greater compression ratio of the turbine, and accordingly a higher output and an improved efficiency, without the use of special compressors.

In gas turbines employed for driving airscrews it is proposed in accordance with the invention to provide a reducing gear between the turbine and the propeller, in such fashion that, with a substantially constant velocity of the propeller, the gas turbine at higher altitudes will run at a greater speed than at lower altitudes. The airscrew may be adapted to the particular conditions prevailing by varying the pitch of the blades of the screw.

A particularly simple means of reducing to practice the idea according to the invention of increasing the circumferential velocity of the gas turbine with increasing height consists in providing between the gas turbine and the propeller a reducing gear having an invariable transmission ratio for driving the propeller at low altitudes, for example for starting purposes or for gaining height,

[Price 1/-]

and also to furnish a clutch device in order, after disengagement of the propeller, to allow the gas turbine at higher altitudes to run at a greater speed, in which case the gas turbine will then act as a pure " rocket " device.

In the case of piston engines an increase in the circumferential velocity would not only fail to improve the compression ratio, but would also represent an increase of the mechanical load on the engine. On the other hand in the case of the highly loaded low-pressure blades of a gas turbine the reduced bending strain on the blades owing to the decrease in the pressure of the air permits at high altitudes of an increase in the load imparted by the centrifugal force and according of an increased circumferential velocity.

The invention will now be described more particularly with reference to the accompanying drawing, which illustrates two possible forms of embodiment.

Fig. 1 is a vertical section taken through a gas turbine aggregate, which in accordance with the invention is furnished with a variable speed gear between the gas turbine and the propeller.

Fig. 2 is a vertical section taken through a gas turbine aggregate, which in accordance with the invention is furnished with an invariable reducing gear and a clutch.

Referring to Fig. 1, the compressor is shown in the form of an axial compressor 1, 2 being the combustion chamber and 3 the turbine. The air enters the compressor 1 at 4 and is heated by the burnt fuel in the combustion chamber 2. The burnt gases drive the turbine 3 and are ejected towards the rear through the diffuser 5. The gas turbine is mounted on the fuselage 16, 17 being the wing of the aircraft.

Connected with the compressor 1 is a gear 6. The shaft 7, on which there are firmly mounted the gear wheels 8 and 9, is connected with the compressor 1. On the key shaft 10, on which is mounted the propeller 11, which is preferably constructed as a variable-pitch propeller, there are mounted to be shiftable the two gear wheels 12 and 13. The gear wheels 12 and 13 may be displaced by means of the fork 14 and the lever mechanism 15 leading to the pilot's seat (not shown), so that the reduced transmission between gas turbine and propeller may be varied. If the shiftable gear wheels 12 and 13 are situated in an intermediate position between the wheels 8 and 9, so that no wheel is in engagement, the gas turbine and the propeller are not connected. The displacement may be effected by hand; it may, however, also be performed by means of a servo-motor. If desired, the variation in the reduced ratio may also take place automatically, for example dependent on the altitude. In the present example a two-speed gear has been shown; there is, however, no limitation with regard to the number of speeds which may be provided. It is also possible to employ a gear in which there is no break in the variation of the speed, for example a hydraulic gear or the like.

Fig. 2 shows a possible embodiment of the invention making use of an invariable reducing gear and a clutch. In the drawing there has been shown a dog clutch. This, however, may also be a spring-controlled friction clutch, an electro-magnetic clutch or a clutch of any other design.

With the compressor 1 there is connected the smaller gear wheel 18, which meshes with the larger gear wheel 19. To the wheel 19 there is firmly connected the disc 20 of the clutch. On the shaft 21 carrying the propeller 11 there is mounted the shiftable clutch plate 22, which may be moved into engagement with the plate 20. The plate 22 may be shifted by means of the fork 23 and the lever mechanism 24.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—

1. A method of adapting the output of gas turbines for propelling aircraft and comprising in substance a compressor, a combustion chamber and a turbine to different altitudes, characterised in that the gas turbine is driven at high altitudes at a greater circumferential velocity than at low altitudes.

2. A gas turbine propelling means for aircraft adapted to drive at least one propeller, characterised in that between the gas turbine and the propeller means are provided which permit of a reduced transmission of any desired ratio, the said transmission being capable of being varied automatically or manually or by combined automatic and manually operable control means.

3. A gas turbine propelling means according to Claim 2, characterised in that an invariable reducing gear and a clutch are fitted between the gas turbine and the propeller.

4. A gas turbine propelling means according to Claim 2, characterised in that between the gas turbine and the propeller there are provided a reducing gear, which is variable automatically or manually or by combined automatic and manual control, and a clutch.

5. A method of adapting the output of gas turbines for propelling aircraft to different altitudes, substantially as hereinbefore described with reference to the accompanying drawing.

6. A gas turbine propelling means for aircraft, substantially as hereinbefore described with reference to the accompanying drawing.

Verbrennungskammer für mit Gleichdruckverbrennung arbeitende Gasturbinen

Patentiert im Deutschen Reich vom 5. März 1936 an
Patenterteilung bekanntgemacht am 18. Mai 1955

Die Erfindung betrifft eine Verbrennungskammer für mit Gleichdruckverbrennung arbeitende Gasturbinenanlagen, die je aus einem Luftverdichter, einer Turbine und der unmittelbar zwischen diesen angeordneten Verbrennungskammer bestehen und die insbesondere zum Antrieb von Luftfahrzeugen verwendet werden sollen. Der Luftverdichter, der als axial oder radial durchströmtes Gebläse ausgebildet sein kann, speist die Verbrennungskammer mit verdichteter Luft, die hier unter Zutritt von Brennstoff verbrennt; die Verbrennungsgase gelangen aus der Verbrennungskammer in die Turbine, beaufschlagen deren Beschaufelung und versetzen den Turbinenläufer in Drehung.

Es ist an sich bekannt, die metallischen Wände der Verbrennungskammer einer Gasturbine mit feuerfestem Baustoff auszukleiden, um so die sonst unter der unmittelbaren Einwirkung der heißen Verbrennungsgase stehenden Wände der Verbrennungskammer vor Zerstörung zu schützen. Es ist ferner vorgeschlagen worden, insbesondere bei Anordnung einer axial durchströmten Turbine und eines unmittelbar von der Turbine angetriebenen axial durchströmten Verdichters, die Verbrennungskammer unmittelbar zwischen der letzten Stufe des Verdichters und der ersten Stufe der Gasturbine anzuordnen. Eine solche Anordnung hat jedoch den Nachteil, daß die Beschaufelung der letzten Stufe des Verdichters und die Beschaufelung der ersten Stufe der Gasturbine unter der unmittelbaren Einwirkung der Wärmestrahlung aus dem Verbrennungsraum stehen. Diese Strahlung ist so groß, daß eine solche Turbinenanlage bisher nicht betriebsfähig war, da die Beschaufelungen des Verdichters als auch der Gasturbine in kürzester Zeit unter der zusätzlichen Einwirkung der Wärmestrahlung aus dem Verbrennungsraum zerstört wurden.

Es ist Aufgabe der Erfindung, eine unmittelbar zwischen Luftverdichter und Turbine einer mit Gleichdruckverbrennung arbeitenden Gasturbine angeordnete Verbrennungskammer zu schaffen, die die schädliche Einwirkung der Wärmestrahlung auf die unmittelbar anschließenden Beschaufelungen vermeidet. Dies wird gemäß der Erfindung dadurch erreicht, daß in den Verbrennungsraum ein Vorsprung oder mehrere Vorsprünge so weit hineinragen, daß sie die wärmeempfindlichen Teile, insbesondere die Beschaufelungen des Luftverdichters und der Turbine, gegen Wärmestrahlung aus dem Verbrennungsraum decken. Hat die Kammer die Form eines Ringes, dann werden die Vorsprünge als ringförmige Rippen oder Wülste ausgebildet, deren radiale Erhebung über die ursprünglichen Mantellinien der äußeren oder inneren Brennraumauskleidung mindestens gleich der Kopfhöhe der letzten Schaufel des Luftverdichters oder der Kopfhöhe der ersten Schaufel der Turbine ist.

In der Zeichnung ist ein Ausführungsbeispiel des Erfindungsgegenstandes im mittleren Längsschnitt durch den Mittelteil einer mit Gleichdruckverbrennung arbeitenden Gasturbine mit ringförmiger Verbrennungskammer veranschaulicht.

Der Luftverdichter 1 ist mit der Gasturbine 2 durch eine Welle 3 verbunden. Um die Welle 3 herum ist innerhalb eines Gehäuses 4 eine ringförmige Verbrennungskammer 5 angeordnet. Die aus der letzten Schaufelreihe 6 des Verdichters 1 austretende verdichtete Luft strömt durch eine ringförmige Öffnung 7 der Verbrennungskammer 5 zu, wo ihr durch eine Düse oder mehrere Düsen 8 Brennstoff zugeführt wird; das Gemisch verbrennt, und die Brenngase strömen durch eine ringförmige Öffnung 9 der Brennkammer 5 zu der ersten Laufschaufelreihe 10 der Turbine 2. Der Verbrennungsraum 5 ist mit Schamotteauskleidungen 11 und 12 versehen, die von Blechen 13 und 14 gestützt werden. Die innere Auskleidung 12 besitzt an ihrem dem Luftverdichter 1 zugewandten Ende eine in den Verbrennungsraum 5 hineinragende ringförmige Rippe 15 und an ihrem der Turbine 2 zugewandten Ende eine entsprechende Rippe 16, während die äußere Auskleidung 11 mit einer ebenfalls ringförmigen wulstartigen Rippe 17 in den mittleren Teil des Verbrennungsraumes 5 hineinragt. Die Querschnittsform der Rippen 15, 16, 17 sowie ihre radiale Erhebung h_1, h_2, h_3 über die ursprünglichen Mantellinien *a* und *i* der äußeren oder inneren Brennraumauskleidung sind im Verhältnis zur Lage und zur Kopfhöhe der Schaufeln 6 und 10 so gewählt, daß sie diese vor der Wärmeanstrahlung aus dem Verbrennungsraum 5 schützen. Durch die wulstartige Formgebung, insbesondere der mittleren Rippe 17, wird gleichzeitig die Durchwirbelung der Brenngase und damit der Verbrennungsvorgang gefördert.

PATENTANSPRÜCHE:

1. Unmittelbar zwischen Luftverdichter und einer mit Gleichdruckverbrennung arbeitenden Gasturbine angeordnete Verbrennungskammer, dadurch gekennzeichnet, daß in den Verbrennungsraum (5) ein Vorsprung oder mehrere Vorsprünge (15, 16, 17) so weit hineinragen, daß sie die wärmeempfindlichen Teile, insbesondere die Beschaufelungen des Luftverdichters und der Turbine gegen Wärmeanstrahlung aus dem Verbrennungsraum decken.

2. Verbrennungskammer nach Anspruch 1, dadurch gekennzeichnet, daß die Kammer (5) die Form eines Ringes hat und die Vorsprünge (15, 16, 17) als ringförmige Rippen oder Wülste ausgebildet sind, deren radiale Erhebung (h_1, h_2, h_3) über die ursprünglichen Mantellinien (*a* und *i*) der äußeren oder inneren Brennraumauskleidung hinaus mindestens gleich der Kopfhöhe der letzten Schaufel (6) des Luftverdichters oder der Kopfhöhe der ersten Schaufel (10) der Turbine ist.

Gasturbinenanlage mit Gleichdruckverbrennung

Patentiert im Deutschen Reich vom 5. März 1936 an
Patenterteilung bekanntgemacht am 21. April 1955

Die Erfindung bezieht sich auf eine insbesondere zum Antrieb von Luftfahrzeugen bestimmte Gasturbinenanlage mit Gleichdruckverbrennung, die im wesentlichen aus einem Luftverdichter, einem Brennraum und der eigentlichen Turbine besteht und bei der diese Bestandteile unmittelbar hintereinander angeordnet sind. Diese Anordnung bringt es mit sich, daß der Brennraum der Gasturbine, in dem während des Betriebes ständig hohe Temperaturen herrschen, in nächster Nähe von wärmeempfindlichen Teilen der Turbinenanlage liegt. Die Erfindung bezweckt, eine solche Gasturbine so auszubilden, daß diese wärmeempfindlichen Teile vor der von dem Brennraum ausgehenden Wärmewirkung geschützt werden und hierbei die Verbindungen des Luftverdichters und der Turbine eine ihren erheblichen Festigkeitsbeanspruchungen gerecht werdende Gestalt und Anordnung erhalten.

Es ist bereits bei Gasturbinen der erwähnten Bauart bekannt, zwischen einer ringförmigen Brennkammer und der leistungsübertragenden Verbindung von Turbine und Verdichter einen mit Luft angefüllten Raum anzuordnen, der einen kleinen, aber angesichts der erheblichen Wärmeeinwirkung des Verbrennungsvorganges unzureichenden Schutz für Turbinenteile, und zwar in erster Linie für die Laufräder der Turbine und des Verdichters und die sie verbindende Welle, bietet. Die diesen Raum anfüllende Luft unterliegt aber selbst einer erheblichen Temperaturerhöhung, da sie die aufgenommene Wärme nicht ableiten kann. Demgegenüber wird die hier vorliegende Aufgabe von der Erfindung in wirksamer Weise dadurch gelöst, daß der die leistungsübertragenden Verbindungen des Verdichters und der Turbine umgebende ringförmige Brennraum innerhalb der Verbindung der Leitvorrichtungen des als umlaufendes Gebläse ausgebildeten Verdichters und der Turbine liegt und diese letztere sowie jene leistungsübertragende Verbindung durch einen Luftstrom gegen die von dem Brennraum ausgehende Wärmeeinwirkung geschützt sind.

Der mit der Erfindung erzielte Wärmeschutz ist also besonders wirksam bei einer solchen Gasturbinenbauart, deren Brennraum ringförmig ausgebildet ist und die leistungsübertragende Verbindung von Luftverdichter und Turbine vollständig umschließt sowie seinerseits innerhalb eines Gehäuses angeordnet ist, das die Leitvorrichtungen des als umlaufendes Gebläse ausgebildeten Verdichters und der Turbine miteinander verbindet. Bei diesem Aufbau der Gasturbine sind in der Hauptsache nur die erwähnten Verbindungen von Verdichter und Turbine gegen die Wärmeeinwirkung des Brennraumes zu schützen. Dies gelingt im vorliegenden Falle um so besser, als die luftdurchströmten Räume sich infolge des Aufbaues der Turbinenanlage unmittelbar an den Verdichter anschließen und daher die Luft ihre Kühlwirkung bei günstigen niedrigen Temperaturen ausüben kann. Außerdem ermöglicht es die Erfindung, den Verbindungen des Verdichters und der Turbine eine Gestalt zu geben, die auch ihre Festigkeit wesentlich steigert.

Die Erfindung ist im nachstehenden an Hand eines Ausführungsbeispieles näher erläutert, welches in der Zeichnung in einem Axialschnitt durch eine Gasturbinenanlage mit Gleichdruckverbrennung dargestellt ist.

Der Läufer des Verdichters 1 ist mit dem Läufer der Turbine 3 durch eine zur Leistungsübertragung dienende Welle 2 verbunden. Zwischen den Teilen 1 und 3 ist ein ringförmiger Brennraum 4 angeordnet, der die Welle 2 vollständig umschließt. Dem Brennraum 4 wird die von dem Verdichter 1 gelieferte Luft sowie der zu ihrer Verbrennung erforderliche Kraftstoff, letzterer durch Leitungen 5, zugeführt; die heißen Brenngase strömen aus dem Brennraum zu der Turbine 3 und versetzen deren Laufrad in Drehung. Die die Leitvorrichtungen 6 und 7 des Verdichters und der Turbine tragenden Teile 8 und 9 sind durch ein tonnenförmiges Gehäuse 10 miteinander verbunden, welches den Brennraum 4 ringförmig umschließt. Zwischen dem Brennraum 4 und der Verbindungswelle 2 ist ein ringförmiger Raum 11 angeordnet, der durch im wesentlichen kegelförmige Räume 12 und 13 mit der Austrittsöffnung der Luft aus dem Verdichter und der Eintrittsöffnung des Brenngasgemisches in die Turbine in Verdung steht. Ferner ist zwischen der Außenseite des ringförmigen Brennraumes 4 und der Innenwand des Gehäuses 10 ein ebenfalls ringförmiger Raum 14 angeordnet, der gleichfalls mit dem Austritt der Luft aus dem Verdichter und dem Eintritt des Brenngasgemisches in die Turbine in Verbindung steht. Die beiden ringförmigen Räume 11 und 14 werden somit von einem Teil der aus dem Verdichter 1 austretenden Luft durchströmt, die von hier aus den den Brennraum verlassenden Brenngasen vor ihrem Eintritt in die Turbine zugesetzt wird. Auf diese Weise entstehen in den ringförmigen Räumen 11 und 14 während des Betriebes der Gasturbine Ströme von ständig aus dem Verdichter zugeführter kalter Frischluft, welche die vom Brennraum ausgehende Wärmeeinwirkung von den die Läufer und die Leitvorrichtungen des Verdichters und der Turbine verbindenden Teile 2 und 10 fernhalten. Durch entsprechende Bemessung der Ein- und Austrittsquerschnitte dieser beiden Luftströme läßt sich die Strömungsgeschwindigkeit der Kühlluft durch die Räume 11 und 14 derart regeln, daß die günstigste Wärmeschutzwirkung der Welle 2 und des Gehäuses 10 erzielt wird. Die ringförmige Ausbildung des Brennraumes 4 und seine unmittelbare Anordnung zwischen Verdichter und Turbine ermöglichen es, dem Gehäuse 10 ebenfalls eine Ringform zu geben, welche den Brennraum völlig umschließt, so daß das Gehäuse der Turbinenanlage gerade in seinem besonders beanspruchten Teil eine einfache und kräftige Gestalt erhält, die ihm eine erhöhte Festigkeit auch gegenüber den mechanischen Beanspruchungen verleiht.

Patentanspruch:

Gasturbinenanlage mit Gleichdruckverbrennung, in deren Längsrichtung ein Luftverdichter, ein Brennraum und eine Turbine hintereinander angeordnet sind, dadurch gekennzeichnet, daß der die leistungsübertragende Verbindung (2) des Verdichters (1) und der Turbine (3) umgebende ringförmige Brennraum (4) innerhalb der Verbindung der Leitvorrichtungen (10) des als umlaufendes Gebläse ausgebildeten Verdichters und der Turbine liegt und diese letztere sowie jene leistungsübertragende Verbindung (2) durch einen Luftstrom gegen die von dem Brennraum ausgehende Wärmeeinwirkung geschützt sind.

Junkers Flugzeug- und -Motorenwerke AG. in Dessau

Vortriebseinrichtung für Luftfahrzeuge

Patentiert im Deutschen Reich vom 14. August 1938 an

Patenterteilung bekanntgemacht am 9. Juli 1942

Die Erfindung bezieht sich auf für Luftfahrzeuge bestimmte Vortriebseinrichtungen, die aus einer Gasturbine, einem von dieser angetriebenen Verdichter für die Verbrennungsluft und einer an die Gasturbine sich anschließenden Rückstoßdüse bestehen.

Es sind Ausführungsformen von Strahlantrieben der angeführten Art bekannt, bei welchen der Austrittsquerschnitt der Rückstoßdüse größer ist als der freie Querschnitt der letzten Turbinenschaufelreihe. Eine solche Ausführung hat zwar den Vorteil, daß die Abmessungen der Gasturbine gering sind; der sich ständig erweiternde Querschnitt der Rückstoßdüse hat aber eine Treibmittelaustrittsgeschwindigkeit zur Folge, die weit über den jetzt üblichen Höchstgeschwindigkeiten von Luftfahrzeugen (etwa 170 m pro Sekunde) liegt. Der Nachteil einer solchen Anlage liegt in dem außerordentlich schlechten Wirkungsgrad, da bekanntlich der Wirkungsgrad einer Rückstoßdüse um so besser wird, je mehr sich Treibmittelgeschwindigkeit und Fahrzeuggeschwindigkeit einander nähern.

Es ist auch schon vorgeschlagen worden, die Rückstoßdüse gegen ihren Austritt zu allmählich zu verengen, so daß der Austrittsquerschnitt der Düse kleiner als der freie Durchtrittsquerschnitt der letzten Beschaufelungsreihe der Gasturbine wird. Die Folge dieser Maßnahme war zwar eine geringere Austrittsgeschwindigkeit des Treibmittels aus der Rückstoßdüse, aber es trat als nicht zu vermeidende Rückwirkung ebenfalls eine durchaus unerwünschte Verringerung der Treibmittelgeschwindigkeit innerhalb der Gasturbine auf. Die Folge war, daß man bei gleicher Leistung den freien Durchtrittsquerschnitt der Gasturbine vergrößern mußte, d. h. daß das Baugewicht der Turbine erhöht und damit das gesamte Triebwerk für die Verwendung im Luftfahrzeug ungeeignet wurde.

Es ist Aufgabe der Erfindung, eine Vortriebseinrichtung für Luftfahrzeuge zu schaffen, welche die Vorteile der bekannten Ausführungsformen besitzt, deren Nachteile jedoch vermeidet.

Gemäß der Erfindung wird diese Aufgabe dadurch gelöst, daß der Austrittsquerschnitt der Rückstoßdüse etwa die gleiche Größe wie der Austrittsquerschnitt der Gasturbine hat.

Ein Strahlantrieb gemäß der Erfindung hat den Vorteil, daß es möglich ist, auch bei Flugzeuggeschwindigkeiten, die etwa in der Größenordnung von 170 m pro Sekunde liegen, einen wirtschaftlichen Wirkungsgrad mit Sicherheit zu erreichen.

Auf der Zeichnung ist ein Ausführungsbeispiel des Erfindungsgegenstandes im Längsschnitt veranschaulicht. Mit 1 ist eine Gasturbine bezeichnet, die einen Verdichter 2 antreibt. Die von diesem verdichtete Luft wird zu einer Brennkammer 3 geleitet, wo sie in Mischung mit dem der Brennkammer zugeführten Brennstoffe zur Verbrennung des letzteren dient. Die aus der Gasturbine 1 austretenden Verbrennungsgase durchströmen ein ringförmig ausgebildetes Rohr 4, und zwar mit einer nahe unterhalb der Schallgeschwindigkeit liegenden Geschwindigkeit. Das ringförmige Rohr 4 dient als Rückstoßer und läßt die Verbrennungsgase durch seinen Querschnitt 5 ins Freie austreten. Der kreisförmige Austrittsquerschnitt 5 ist so bemessen, daß er etwa gleich dem Austrittsquerschnitt 6 der Gasturbine ist und daß zugleich der Umhüllung 7 der gesamten Anordnung eine strömungstechnisch günstige Gestalt gegeben wird.

PATENTANSPRUCH:

Vortriebseinrichtung für Luftfahrzeuge, bestehend aus einer Gasturbine, einem von dieser angetriebenen Verdichter für die Verbrennungsluft und einer an die Gasturbine sich anschließenden Rückstoßdüse, dadurch gekennzeichnet, daß der Austrittsquerschnitt der Rückstoßdüse etwa die gleiche Größe wie der Austrittsquerschnitt (6) der Gasturbine (1) hat.

Heißstrahltriebwerk zum Vortrieb von Luftfahrzeugen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 6. März 1943 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 19. März 1953
Patenterteilung bekanntgemacht am 22. Oktober 1953

Die Erfindung bezieht sich auf Heißstrahltriebwerke zum Vortrieb von Luftfahrzeugen, bestehend aus einem Verdichter, Brennkammern und einer den Verdichter antreibenden Gasturbine mit anschließender Rückstoßdüse, bei welchem die Kraftstoffzuteilung in Abhängigkeit von der Drehzahl gesteuert wird, und betrifft ein Verfahren zur Regelung.

Die bei Dampfturbinen bekannte Regelung in Abhängigkeit von der Drehzahl läßt sich zweckmäßig auf Gasturbinen übertragen, welche in Heißstrahltriebwerken der obengenannten Art eingebaut sind. Jedoch ist hierbei zu berücksichtigen, daß das Treibmittel für diese Gasturbinen (im Gegensatz zu dem Treibmittel der Dampfturbinen, das aus dem Kesselhaus in stets gleicher Beschaffenheit anfällt) im Heißstrahltriebwerk selbst aufbereitet wird und daß daher die Höchsttemperatur des Treibmittels mit Rücksicht auf die Turbinenbeschaufelung durch eine zusätzliche Regeleinrichtung begrenzt werden muß.

Regelungseingriffe für die Temperatur sind aber, wie die Erfahrung zeigt, in Heißstrahltriebwerken praktisch schwierig durchzuführen, weil der Fühlverzug eines vor der Gasturbine angeordneten Temperaturfühlers im Verhältnis zu den Anforderungen des Triebwerkes sehr groß ist.

Die geschilderten Schwierigkeiten können gemäß der Erfindung dadurch behoben werden, daß die Rückstoßdüse so ausgelegt ist, daß im oberen Leistungsbereich des Triebwerkes das Druckverhältnis des Treibmittels in der Ausströmdüse

Einrichtung zum Vermeiden des Abreißens der Strömung in Axialverdichtern

Patentiert im Gebiet der Bundesrepublik Deutschland vom 2. März 1943 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 1951)
Patentanmeldung bekanntgemacht am 7. Mai 1953
Patenterteilung bekanntgemacht am 4. Oktober 1956

Die Erfindung bezieht sich auf eine Einrichtung zum Vermeiden des Abreißens der Strömung in axial durchströmten Verdichtern.

Bekanntlich können in axial durchströmten Verdichtern große Mengen bei im Verhältnis zu radial durchströmten oder gar zu Kolbenverdichtern wesentlich kleineren Maschinenabmessungen verarbeitet und dabei günstige Wirkungsgrade erzielt werden. Diesen Vorzügen steht nachteilig die Tatsache entgegen, daß sich günstige Wirkungsgrade nur in einem verhältnismäßig schmalen Betriebsbereich erreichen lassen; ein Nachteil, der sich mit der Anzahl der Stufen steigert.

Fördert nämlich ein axial durchströmter Verdichter eine größere Menge, als seinem günstigsten Betriebspunkt entspricht, d. h. als der Menge entspricht, für welche er ausgelegt ist, dann sinken Förderdruck und Wirkungsgrad zunächst langsam, dann immer schneller ab. Dieses Absinken ist zwar energiemäßig unerwünscht, führt aber noch zu keinen Betriebsschwierigkeiten, wenn eine genügend große Arbeitsleistung zum Antrieb des Verdichters zur Verfügung steht und die geringere Verdichtung in Kauf genommen werden kann. Wesentlich ungünstiger liegen jedoch die Verhältnisse, wenn der Verdichter eine zu kleine Menge verarbeiten soll.

Figure 9.80: Examples of jet engine patents by Siegfried Decher.

Bruno Bruckmann (Austrian, 1902–1997), Peter Kappus (German, 1910–2008), Hermann Östrich (German, 1903–1973), R. Walter Brisken (German, 1914–2011), and others developed the BMW 003 axial-flow turbojet engine (first run in 1940, Fig. 9.81). At least 3500 BMW 003 engines were produced during the war. The BMW team also built prototypes of the larger, more advanced BMW 018 axial-flow turbojet engine, and they were developing the BMW 028 turboprop engine (p. 1748).

Norbert Riedel (Austrian, 1912–1963) built turbojet starter motors and also motorcycles.

Karl Leist (German, 1901–1960) built and demonstrated the first functional turbofan engine, the Daimler-Benz DB 007, also known as the Zweikreis Turbinen-Luftstrahltriebwerk ZTL 6001 (began development 1939, first run 1 April 1943). See pp. 1746, 5233–5241. At least three DB 007 turbofan engines were produced. The Heinkel company was also developing turbofan engines.

György Jendrassik (Austro-Hungarian, 1898–1954) designed the Jendrassik Cs-1 turboprop engine in 1937 and first ran it in a test stand in 1940 (Fig. 9.83).

During the war, there were several notable turboprop engine development projects, including the Jumo 022 (p. 1748), BMW 028 (p. 1748), and Heinkel He S 021 (a turboprop version of the He S 011, p. 1731).

Ferdinand Brandner (Austrian, 1903–1986) worked at Junkers during the war developing engines such as the Jumo 012 turbojet and Jumo 022 turboprop. After the war, he built copies (NK-12) of the Jumo 022 turboprop in Russia and then developed jet engines (such as the Egyptian E-300) in several other countries. See Fig. 9.85.

According to official histories, none of the turbofan or turboprop engines were used on aircraft before the end of the war. However, historians should carefully investigate whether some of the turbofan or turboprop work may have actually progressed further during the war, and how much it influenced postwar work on turbofan and turboprop engines, in view of:

1. The high priority placed on intercontinental jet bombers in the final years of the war.

2. The significantly higher fuel efficiency and hence longer range enabled by turbofan and turboprop engines compared to turbojet engines.

3. The great secrecy with which both wartime German scientists and postwar Allied investigators would have handled jet engine technology that was so advanced and had such strategic implications for intercontinental bombing.

For more information on wartime programs to develop intercontinental jet bombers, see Sections E.1 and E.6.

Figure 9.85: Ferdinand Brandner worked at Junkers during the war developing engines such as the Jumo 012 turbojet and Jumo 022 turboprop. After the war, he built copies (NK-12) of the Jumo 022 turboprop in Russia and then developed jet engines (such as the Egyptian E-300) in several other countries.

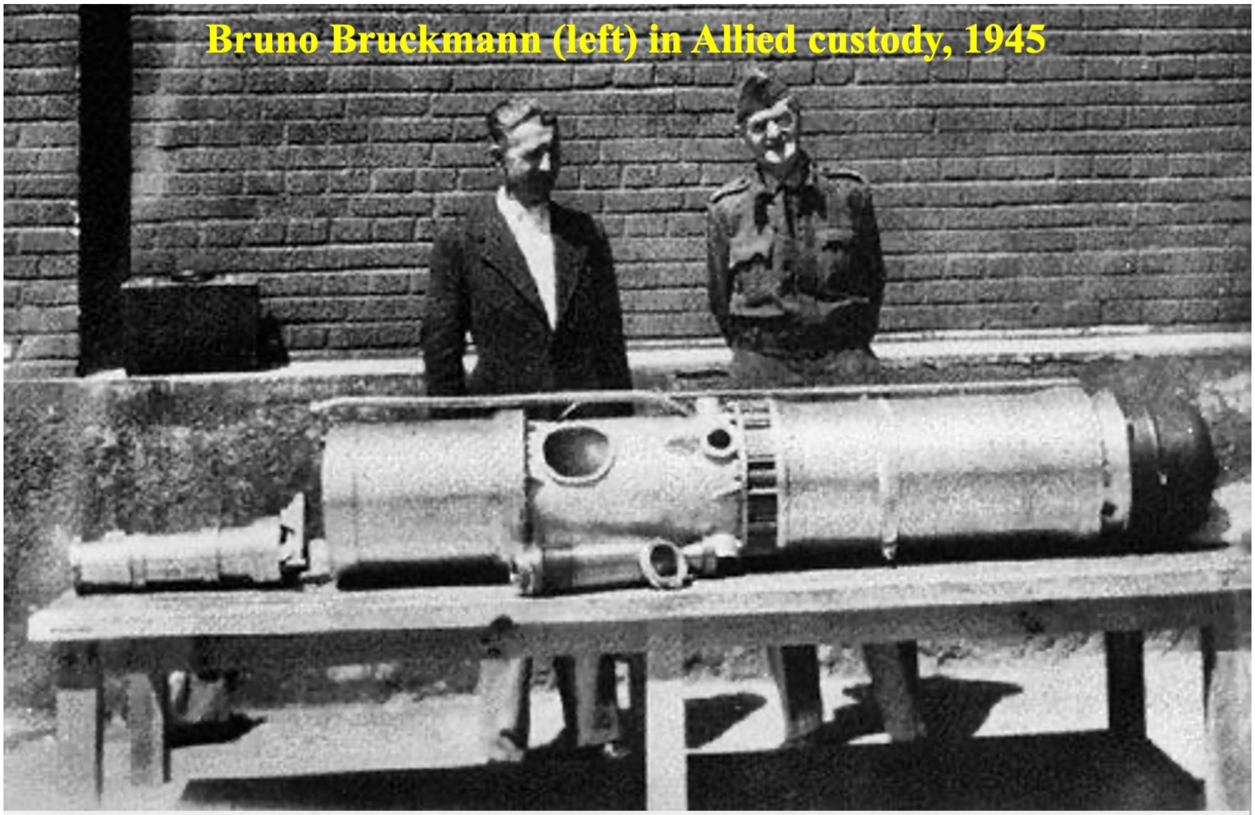
After the war, Bruno Bruckmann and Peter Kappus from the BMW group moved to the United States and designed jet engines for General Electric. See Figs. 9.86–9.97. Some of their postwar GE engines included the J47 turbojet engine (first run 1947, while Bruckmann and Kappus were still officially based at Wright Field but working with GE in nearby Evendale, Ohio), J73 turbojet engine (first run 1953), J79 or CJ805 turbojet engine (first run 1954), and TF35 or CJ805-23 turbofan engine (first run 1956). One of the most impressive projects by Bruckmann and Kappus was the YJ-93 engines for the Mach 3+ XB-70 Valkyrie (Figs. 9.89–9.90). The XB-70 made its first flight in 1964, and *Life* magazine highlighted Bruckmann's accomplishments [Wheeler 1965]:

> Bruno Bruckmann. G.E. assigned him to build the engines for the B-70. Bruckmann was born in 1902, the son of a pulp mill director, in the village of Mühlbach in the Italian-Austrian Alps. With an engineering degree from the Technische Hochschule of Munich he eventually went to work at the Bayerische Motoren Werke designing aircraft engines. He started building primitive jets for Hitler in 1939 and, by 1941, hitched his first two practicable engines to a Messerschmitt. The jets were so feeble that a standard piston engine had to be glued on for insurance.
>
> When the war ended, B.M.W. had been bombed out of four different plants and the jet works had been moved for safekeeping into salt mines 2,000 feet underground. In 1946 the U.S. Air Force "invited" Bruckmann to come for a lengthy visit to the U.S. He is tall, precise, silver-haired and looks and sounds like a casting director's dream of a Prussian nobleman.
>
> "It wasn't a social invitation. Perhaps I could have refused it—although that might have made the Air Force unhappy," Bruckmann said recently, "But I was not going to refuse. After all, I was aware the Russians might *invite* me." [...]
>
> Most of the other revolutions Bruckmann wrought are classified Pentagon secrets. They include such exotic concepts as the internal use of rare new alloys, or using fuel to soak the heat out of lubricating oils, or an exacting process of tuning lengths of pipe like a violin to cut out sympathetic vibrations. The results add up to a monster engine, doubling the output of its predecessor and delivering 30,000 pounds of thrust, or six pounds of push for every pound it weighs, capable of sustained operation in ferocious temperatures of more than 2,500^o F in the afterburners. They called it the YJ-93.

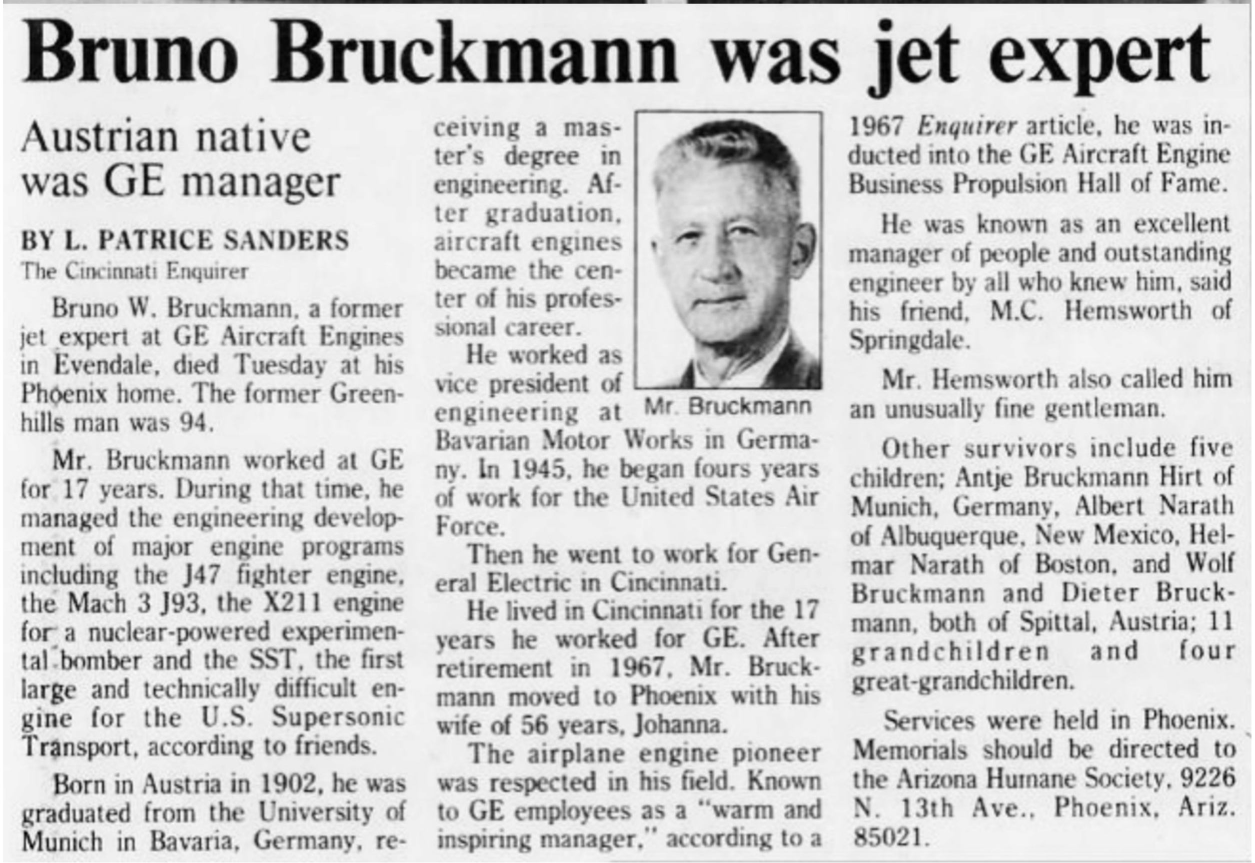
Bruckmann and Kappus even designed jet engines that heated the air via nuclear fission instead of chemical combustion reactions. For example, they developed the GE X211 nuclear turbojet engine, which was first demonstrated in 1958 (Fig. 9.91). Two GE X211 engines would have powered the proposed Convair NX-2 bomber, which was cancelled before it could be completed [Carpenter 2003].

Kappus was also a longtime designer and proponent of vertical takeoff and landing (VTOL) aircraft. In September 1957 (before Sputnik!), he filed a patent application on a VTOL vehicle that was ultimately implemented as the Lunar Landing Research Vehicle to train astronauts to land the Apollo Lunar Module (first flight 1964, with the vehicle's legs and pilot's position modified to resemble the final Lunar Module design, Fig. 9.95). Beginning in 1957, he filed several patent applications on VTOL aircraft with downward-pointing ducted fans in the wings and/or body (Figs. 9.96–9.97). That approach was successfully implemented in aircraft such as the Ryan XV-5 Vertifan (first flight 1964) and the Lockheed Martin F-35B (first flight 2008).

After the war, R. Walter Brisken from the wartime BMW jet engine group also moved to General Electric, where he developed the GE LM2500 gas turbine power plant that has been widely employed in ships and industrial applications since the 1960s (Fig. 9.98).



Bruno Bruckmann (left) in Allied custody, 1945



Bruno Bruckmann was jet expert

Austrian native was GE manager

BY L. PATRICE SANDERS
The Cincinnati Enquirer

Bruno W. Bruckmann, a former jet expert at GE Aircraft Engines in Evendale, died Tuesday at his Phoenix home. The former Greenhills man was 94.

Mr. Bruckmann worked at GE for 17 years. During that time, he managed the engineering development of major engine programs including the J47 fighter engine, the Mach 3 J93, the X211 engine for a nuclear-powered experimental bomber and the SST, the first large and technically difficult engine for the U.S. Supersonic Transport, according to friends.

Born in Austria in 1902, he was graduated from the University of Munich in Bavaria, Germany, receiving a master's degree in engineering. After graduation, aircraft engines became the center of his professional career.

He worked as vice president of engineering at Bavarian Motor Works in Germany. In 1945, he began fours years of work for the United States Air Force.

Mr. Bruckmann

Then he went to work for General Electric in Cincinnati.

He lived in Cincinnati for the 17 years he worked for GE. After retirement in 1967, Mr. Bruckmann moved to Phoenix with his wife of 56 years, Johanna.

The airplane engine pioneer was respected in his field. Known to GE employees as a "warm and inspiring manager," according to a 1967 *Enquirer* article, he was inducted into the GE Aircraft Engine Business Propulsion Hall of Fame.

He was known as an excellent manager of people and outstanding engineer by all who knew him, said his friend, M.C. Hemsworth of Springdale.

Mr. Hemsworth also called him an unusually fine gentleman.

Other survivors include five children; Antje Bruckmann Hirt of Munich, Germany, Albert Narath of Albuquerque, New Mexico, Helmar Narath of Boston, and Wolf Bruckmann and Dieter Bruckmann, both of Spittal, Austria; 11 grandchildren and four great-grandchildren.

Services were held in Phoenix. Memorials should be directed to the Arizona Humane Society, 9226 N. 13th Ave., Phoenix, Ariz. 85021.

BMW Flugmotorenbau Gesellschaft m. b. H. in München
Verfahren zur Verbesserung der Kühlwirkung bei mehrreihigen luftgekühlten Sternmotoren

Patentiert im Deutschen Reich vom 24. Februar 1938 an
Patenterteilung bekanntgemacht am 18. September 1941

Gemäß § 2 Abs. 2 der Verordnung vom 28. April 1938 ist die Erklärung abgegeben worden, daß sich der Schutz auf das Land Österreich erstrecken soll.

Bei mehrreihigen Sternmotoren mit Luftkühlung bereitet die Kühlung der hinter dem ersten Zylinderstern liegenden Zylinder der folgenden Zylindersterne Schwierigkeiten, da der erste Zylinderstern stark abschirmend wirkt. Man verwendet daher besondere Leitblechanordnungen und besonders ausgebildete Haubenverkleidungen, um eine ausreichende Kühlwirkung der hinteren Zylinderreihen einigermaßen sicherzustellen. Eine Durchmesservergrößerung der Verkleidungsanlage, um den Luftdurchsatz zu erhöhen, ist in vielen Fällen nicht mehr tragbar. Durch eine solche Vergrößerung steigt der Stirnwiderstand, so daß die Fluggeschwindigkeit erheblich heruntergeht. Der Verlust an Fluggeschwindigkeit steht in keinem Verhältnis zu dem verhältnismäßig geringen Kühlgewinn.

Es hat sich nun gezeigt, daß durch die höhere Temperatur der im Windschatten liegenden Zylinderteile diese frühzeitig zu Klopferscheinungen neigen. Damit ist bekanntlich auch ein rascher Temperaturanstieg der betreffenden Zylinder verbunden, so daß eine Kühlung mit den normalen Mitteln nicht mehr möglich ist.

Es würde in der Regel genügen, diejenigen Zylinder, die schlechter gekühlt sind, nur um wenige Grad in ihrer Temperatur abzusenken, um zumindest die frühzeitige Klopfneigung zu unterdrücken. Ist ein Triebwerk dann so ausgerichtet, daß sämtliche Zylinder annähernd einen gleichen Temperaturverlauf besitzen, dann ist in der Regel mit den normalen Mitteln, ohne eine Durchmesservergrößerung vornehmen zu müssen, eine wirksame Kühlung möglich. Es wird in einem solchen Fall keiner der Zylinder durch vorzeitige Klopfneigung einen raschen Temperaturanstieg mehr besitzen, der die übrigen Zylinder in Mitleidenschaft zieht

VTOL AIRCRAFT

Peter Gottfried Kappus, Cincinnati, Ohio, assignor to General Electric Company, a corporation of New York

Application September 6, 1957, Serial No. 682,328

6 Claims. (Cl. 244—23)

The present invention relates to a VTOL aircraft and, more particularly, to a vertical take-off and landing aircraft using a ducted-fan engine in which a smooth external vehicle surface completely encloses all the rotating and control elements.

In recent years, much emphasis has been placed on the development and perfection of the so called VTOL or vertical take-off and landing type of aircraft. This is an aircraft that requires no runway and takes off directly upward or substantially so and is then directed forwardly by either shifting weight or by suitable control surfaces to provide a horizontal component of force. In some propeller driven types of VTOL aircraft, the whole vehicle or engine is tilted for horizontal flight. The advent of the jet engine has indicated it to be a desirable powerplant for such an aircraft if suitable control means and size can be obtained in an efficient vehicle to make the project feasible. As is well known, the jet engine consumes relatively high quantities of fuel which can be a distinct disadvantage in VTOL aircraft which are designed for subsonic or low subsonic forward operations in that the vehicles have a very short range of operation. Another disadvantage is that such vehicles are inherently unstable in flight. Consequently, there is a need for a vehicle of this type which will have a clean outward appearance within practical size limits and be capable of sustained flight at high subsonic operation with a practical specific fuel consumption.

Many of the VTOL aircraft of the type discussed here are nothing more than flying engines with a load platform to carry the pilot. Devices of this type, which have thus far been perfected, have been either propeller operated or, in those employing jet engines, have been limited by very short flight duration, time, and relatively low speeds.

It is a primary object of the present invention to provide a VTOL aircraft which will have a much higher sustained operation time with economy of operation in fuel consumption and which is capable of higher flight speeds than similar aircrafts heretofore known.

Another object of the invention is to provide such a vehicle which has a high ratio of fuel load to gross weight and is self contained in that all the rotating parts and controls are completely enclosed within the vehicle itself to prevent external drag and provide completely flexible control.

A further object is to provide such a vehicle which attains these objectives by the use of a ducted fan engine in combination with enclosed control surfaces in the nozzle or exhaust stream within the confines of the vehicle.

Briefly stated, in accordance with my invention, I provide a vehicle housing which carries a load sustaining platform at one end and has a nozzle at the opposite end. Within the housing, there is provided a gas generator with a ducted fan which is separate from the generator and provides for a larger mass flow and economy of operation. This is attained within a vehicle of relatively small diameter for its thrust capabilities.

2

My invention will be better understood from the following description taken in connection with the accompanying drawing and its scope will be pointed out in the appended claims.

In the drawing:

Figure 1 is an elevation view of the VTOL aircraft of the instant invention as it would appear on the ground and,

Figure 2 is a cross sectional view illustrating the internals of such an aircraft.

Referring first to Figure 1, a VTOL aircraft of the type described in the instant invention, may be termed a flying engine, since, in effect, it consists of nothing more than a barrel-like housing generally indicated at **10**, which is supported at one end in a vertical position on the ground by suitable supporting means **11** and carries at the other or upper end a load carrying platform **12** which may accommodate the pilot **13**. The pilot may or may not be enclosed by a suitable protecting canopy **14**. In order to pilot the aircraft, a suitable control panel **15** is provided.

As shown in Figure 2, housing **10** may be a tubular housing of generally cylindrical shape although it is not limited to the cylindrical form. Coaxially arranged within the housing is a powerplant of the jet engine type. This may preferably comprise a gas generator engine of the axial flow type including a compressor section **16**, a combustion section **17** which may be annular or cannular as shown, and a turbine section **18**. This structure which, in effect, is a turbojet engine minus the nozzle is generally referred to as the main engine.

In order to provide for economical operation with relatively low specific fuel consumption within a vehicle of much smaller diameter than heretofore believed necessary, I employ a powerplant of the ducted fan type. This may comprise a free rotating turbine **20** having fan blades **21** on the extremity thereof.

For compactness of operation and high ratio of fuel load to gross load, fuel tanks **22** may form the outer casing of the gas generator or main engine. The fuel tanks are supported within housing **10** by means of struts **23** and **24**. In order to provide for aligned rotation of the turbine and compressor, bearing **25** is supported from the fuel tanks by struts **27** and from the housing by strut **28** and bearing **26** is supported from the fuel tank by strut **29**. The engine shaft **30** is supported in these bearings.

The increased mass flow obtained by the use of the ducted fan engine is obtained by the provision of the bypass duct **31** between the housing and the engine in which ducted fan blades **21** compress additional air for increased mass flow. Fan blades **21** are driven by free turbine or turbines **20** which are supported in bearing **32** separate from bearing **26**. Thus the turbine **20** is disconnected from and freely rotatable with respect to the main engine. It is to be noted that the free fan may comprise a single stage, or plurality of stages as shown which stages may rotate in the same direction as the main engine or in the opposite direction. In addition, if a plurality of stages is provided, the stages may rotate in opposite directions relative to one another. The direction of rotation will be determined by the characteristics desired of the particular powerplant.

In order to provide air for the powerplant as thus far described, the periphery of the housing **10** is supplied with a plurality of openings preferably in the upper portion thereof which openings may be covered by screen member **33**. Thus, substantially the whole periphery of the housing member **10** is an air intake surface. The air for the main engine flows upwardly around struts **24**

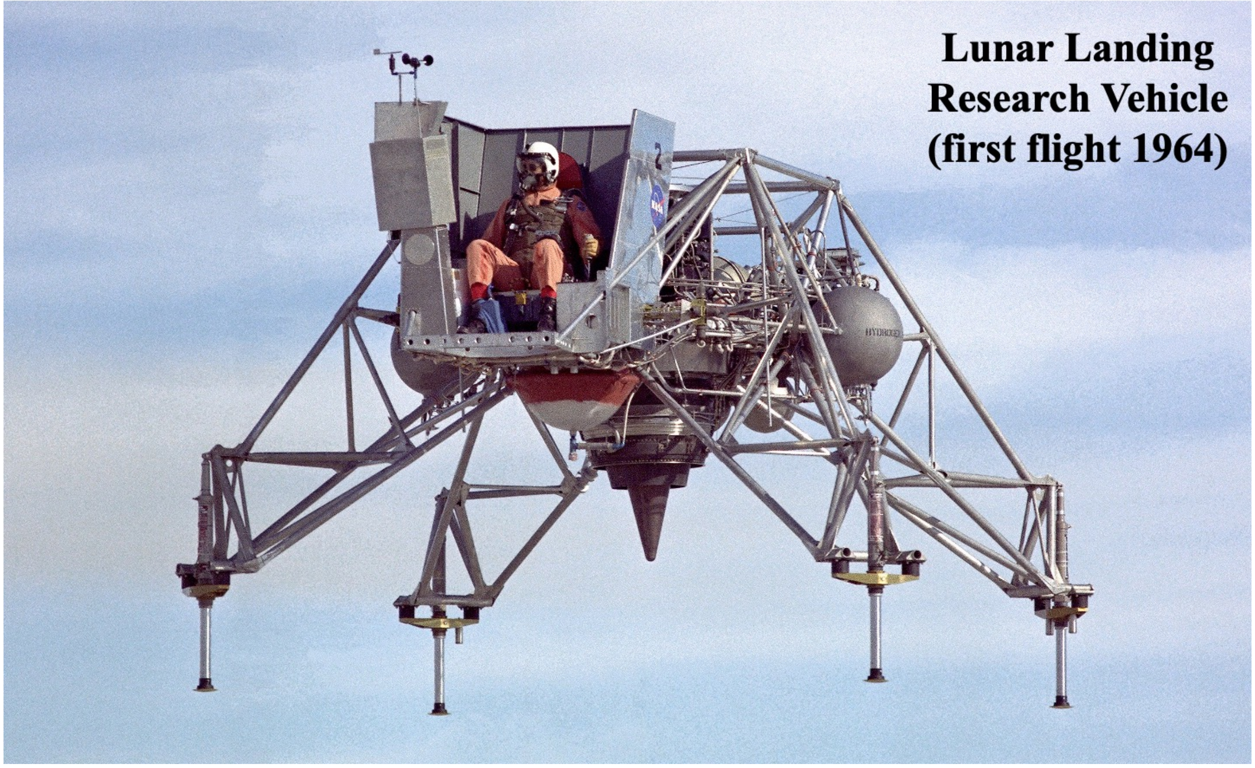

Figure 9.95: In September 1957 (before Sputnik!), Peter Kappus filed a patent application on a VTOL vehicle that was ultimately implemented as the Lunar Landing Research Vehicle to train astronauts to land the Apollo Lunar Module (first flight 1964, with the vehicle's legs and pilot's position modified to resemble the final Lunar Module design).

Ryan XV-5 Vertifan with 1 fan in each wing + 1 fan in the nose (first flight 1964)

Lockheed Martin F-35B with 1 fan behind cockpit (first flight 2008)

Figure 9.96: Beginning in 1957, Peter Kappus filed several patent applications on VTOL aircraft with downward-pointing fans in the wings and/or body (see also Fig. 9.97). That approach was successfully implemented in aircraft such as the Ryan XV-5 Vertifan (first flight 1964) and the Lockheed Martin F-35B (first flight 2008).

ABSTRACT: A V/STOL aircraft comprises a fuselage having tandem wings which are offset lengthwise and vertically. Identical propulsion units are provided in each wing half. Each power unit comprises a pair of gas generators mounted respectively above and below the wing half and a pair of lift fans mounted within the wing structure on opposite sides of the engines. A valve system diverts the hot gas stream of the engines into a plenum chamber formed integrally with the wing structure. The hot gas streams are then directed from the plenum chamber to a tip turbine which powers the lift fans when vertical thrust is desired in operation of the aircraft. When forward speed of the aircraft is great enough for the aircraft wings to have sufficient lift, the hot gas streams are directed through propulsive nozzles providing a forward thrust component. In cruise, one engine of each power unit could be shut down. Each engine and each lift fan has emergency capacity which is automatically brought into play in the event of a failure of a lift fan or engine, with proper adjustments being made to the other power units to maintain balance and controlled operation of the aircraft in the lift mode.

R. Walter Brisken (1914–2011) developed the GE LM2500 gas turbine power plant for ships and industrial applications

R. WALTER BRISKEN

August 8, 1986
1356 SHIPWATCH
AMELIA ISLAND PLANTATION
FLORIDA, 32034

Officer in Charge of Construction, TRIDENT
Attention: Code 09XE3
293 Point Peter Road
St. Marys, Georgia 31558

Subject: Public Hearing for Draft Third Supplement Environmental Impact Statement "St. Marys Entrance Channel Dredging", held at Fernandina Beach High School, Fernandina Beach, Florida on July 31, 1986.

Dear Sir!

The following is my written statement concerning the above subject.

After 41 years of research, engineering development, project leadership and management I retired six and a half years ago as Program General Manager, Marine Projects, General Electric Co. in which position I had the full responsibility for the LM 2500 marine engine which now powers all the non-nuclear powered destroyers, frigates and hydrofoils of the US Navy built since 1970 and currently being built. When I retired at the end of 1979 Vice Admiral, US Navy C. R. Bryan, Commander Naval Sea Systems Command wrote me a letter in which he said "I can not help but think that the Navy is losing a very good friend".

Figure 9.98: R. Walter Brisken developed the GE LM2500 gas turbine power plant for ships and industrial applications.

Other BMW aircraft engine experts who moved to the United Stated included Rudolf Ammann (German, 19??–19??, an expert on piston aircraft engines and on wind turbines) and Christoph Soestmeyer (German, 19??–19??, an expert on jet engine testbeds to simulate high altitudes, such as the wartime BMW Herbitus facility in Munich).

Some other BMW jet experts, such as Hermann Östrich, Hans-Georg Münzberg (Austrian/German, 1916–2000), August Wilhelm Quick (German, 19??–19??), Otto David (German, 19??–19??), and others, developed jet engines and jet aircraft in France after the war (Fig. 9.99).

René Lorin (French, 1877–1933) proposed the general notion of a ramjet in 1913 but did not have the resources to pursue the topic; ramjets are sometimes called Lorin tubes after him. In Germany, separate, well-funded teams led by Otto Pabst (German, 19??–19??), Eugen Sänger (Austrian, 1905–1964), and Hellmuth Walter (German, 1900–1980) developed and demonstrated fully functional ramjets during World War II. Figure 9.100 shows Sänger's ramjet being successfully tested in 1942. In the United States, Fritz Zwicky (Swiss, 1898–1974) designed and proposed ramjets, but was unable to find any financial or political support for such an innovative concept.

Just as ramjets work best at supersonic speeds but can be modified to operate at hypersonic speeds as scramjets, they can also be modified to work at subsonic speeds as pulsejets, as shown in Fig. 9.53. With no active compressor and only minimal compression from stagnation effects, the combustion products could easily escape through the front diffuser of the engine instead of through the rear nozzle as intended. To avoid this problem, the diffuser must be open when taking in air, but closed when combustion occurs. This means that combustion must occur in a pulsed rather than continuous fashion, and the front air inlet must cycle open and closed at the appropriate times during each pulse. In order to imitate continuous combustion, the pulses must occur at fairly high frequency, typically ∼40–50 cycles per second (or Hertz, Hz). The air intake generally uses mechanical shutters or valves that can be opened and closed at such a high frequency.

Paul Schmidt (German, 1898–1976) created the first major pulsejet engine of note—the Argus As 014 engine that ended up being used in the V-1 missile, which is discussed in Section 9.6. Figure 9.101 shows an Argus engine with one side cut open. The engine used mechanical shutters and a pulse frequency of 43 Hz to produce 3.3 kN (750 lb) of thrust during flight. Since there was no active compressor, a steam-driven catapult was used to rapidly accelerate the V-1 to an airspeed where its engine could achieve self-sustaining flight (p. 5279). The V-1 was essentially the world's first cruise (non-ballistic) missile, and became known as the "buzz bomb" because of its engine's very loud and distinctive frequency. The engine's low energy efficiency (due to its minimal compression of the intake air) and inherent problems with vibration were offset by its very simple design and attendant low cost and high thrust-to-weight ratio.

During the Third Reich, many of the jet engine and jet aircraft development programs were funded by the Reichsluftfahrtministerium (Reich Ministry of Aviation). Two individuals there who were especially important in championing and guiding the jet programs were Helmut Schelp (German, 19??–19??) and Hans Mauch (German, 1906–1984). After the war, Helmut Schelp went to the United Kingdom, and Mauch went to the United States. Ultimately Mauch became much better known for his wartime and long postwar work developing prosthetic limbs, rather than for his earlier work on jets; see Sections 2.7.2 and A.2.

EXPLOITATION OF GERMAN SCIENTISTS BY FRANCE AND RUSSIA

The following typical cases are presented as evidence of French-Russian efforts and successes and American failures in contracting top ranking German scientists and technicians.

1. Case "Oestrich" (France)

a. Dr. Oestrich has been in charge of jet development at BMW. Shortly before the Russian invasion he was taken to Munich by American authorities. After a long and fruitless waiting period during which Oestrich hoped for an American contract, he entered into negotiations with France. Dr. Oestrich had secured the cooperation of his best collaborators by private contracts in advance. In November 1945 Oestrich and these collaborators, first class specialists throughout, went as a group of 25 to Lindau in the French occupied zone. Previously, Oestrich had shown his French contract to one of the scientists now at Wright Field. According to this contract, the French government made the most generous arrangements to immediately accomodate these scientists and their families. The contract runs for a period of 4 years, during which time Oestrich expects to employ approximately 1,000 people. Dr. Oestrich is sole chief of the undertaking and directly responsible to the respective French Ministry. He receives the same salary as in Germany, shares substantially in the profits derived from his designs and patents, and has full authority to hire and fire as he pleases. According to latest reports, Oestrich already has gathered a staff of 500, is traveling freely throughout the American Zone and has succeeded in contracting some of BMW's and Daimler-Benz's top ranking engineers. It may be safely assumed that it is Oestrich's intention and immediate aim to gather all leading German jet engineers still in Germany under French contracts in France.

b. One of the scientists now at Wright Field is Dr. Anselm Franz, former chief of jet development at Junkers, and designer of the Junkers 004. In view of long term future projects in this country, Dr. Franz is in need of some of his top ranking specialist collaborators. Some of the people who fall in this category, particularly Dr. Siegfried Decher, have been officially requested by Dr. Franz some time ago. Due to the lack of any notification by American authorities upon this request, or by Dr. Franz himself -- Franz is unable to write because of present restrictions -- Decher has meanwhile accepted a French contract with Dr. Oestrich. A few days ago Dr. Decher informed Dr. Franz via Mrs. Franz by wire that France intends very shortly to move all German scientists to the interior of France (Pyrenees), and

9.3.2 Jet Aircraft

Willy Messerschmitt (German, 1898–1978), Ludwig Bölkow (German, 1912–2003), and Woldemar Voigt (German, 1907–1980) headed the team that developed and mass-produced the Messerschmitt Me 262 Schwalbe (Swallow) twin-engine jet fighter, which was first flown in 1942; see Fig. 9.102. By the end of the war, there were highly sophisticated underground plants for mass-producing Me 262 fighters despite Allied bombing, such as those at St. Georgen/Gusen and Kahla (pp. 4967–4969, 5214–5217). An upgraded version of the Schwalbe with integrated jet engines and a two-person cockpit, Me 262 HG III, was designed but apparently not built before the end of the war (Fig. 9.103). After the war, Messerschmitt developed jet aircraft for Spain, Egypt, and West Germany; Bölkow created jets and missiles in West Germany; and Voigt worked in the United States.

Walter Blume (German, 1896–1964) led the team that developed and mass-produced the Arado Ar 234 Blitz (Lightning) twin-engine jet bomber, which was first flown in 1943; see Fig. 9.104. After the war, he played a critical role in developing jet fighters and bombers in the Soviet Union.

The German brothers Walter Horten (1913–1998) and Reimar Horten (1915–1994) developed advanced flying wing jet aircraft, as shown in Figs. 9.105–9.106.[9] Their earliest prototypes were sailplanes, before they were able to obtain jet engines from Jumo or BMW. They designed and built the twin-engine Horten Ho 229 stealth fighter, which they first demonstrated in 1944. They also designed the six-engine Horten H.XVIII intercontinental stealth bomber in 1944; there is some evidence that it may have been built or under construction when the war ended—see pp. 5227–5231. After the war, Reimar Horten developed aircraft in Argentina while Walter Horten developed aircraft in West Germany. In addition to the all-wing approach, an important feature of the Horten brothers' designs was their stealthy reduced radar cross sections, due to vehicle shapes that minimized direct radar returns, buried engines, minimization of metal components, and use of special coatings. (For more information on the German creation of stealth technology, see Section 6.8.2.) The strong influence of the Horten brothers' designs was felt even many decades later in the U.S. stealth fighter and stealth bomber.

As shown in Fig. 9.107, postwar jet fighters such as the U.S. F-86 Sabre and Soviet MiG-15 were directly derived from wartime German designs such as the Messerschmitt Me P.1101 (designed by Woldemar Voigt and Ludwig Bölkow) and Focke-Wulf Ta 183 (designed by Hans Multhopp and Kurt Tank).

In fact, the F-86 was developed by Edgar Schmüd (German, 1899–1985), an aircraft designer who immigrated to the United States before World War II (pp. 1679, 1688). In addition to the Me P.1101 and Focke-Wulf Ta 183, Schmüd drew upon other German-developed technologies. As just one example, in 1952, *Life* magazine reported [Campion 1952]:

> In the summer of 1945 two peculiarly interesting objects, sent by air force intelligence, arrived at the North American Aviation Co.'s Los Angeles plant. One was the wing of the latest German jet fighter, a Messerschmitt 262, and its batlike design was startling to the company's engineers who had never seen anything like it on a plane before. The other, of even greater interest, was a secret record of German wind-tunnel experiments

---

[9] Horten and Selliger 2012; Jorgensen 2009; Myhra 1998b; Shepelev and Ottens 2015.

> on the aerodynamic behavior of radically swept-back wings. Conclusive and exhaustingly thorough, the data (which the Russians also lifted from the files of the Luftwaffe) saved North American three laborious years of research in designing the Air Force's fastest fighter now in operation, the F-86 Sabre jet. As sketched out on the company's drawing boards, the F-86 was to be equipped with the conventional straight wing. But by adapting the German innovations, North American was able to convert its design from straight to swept-back in only four weeks.

Edgar Schmüd also created the North American P-51 Mustang (1940, based on the 1935 Messerschmitt Bf 109), the North American F-100 Super Sabre (1953), the Northrop F-5 Freedom Fighter (1959), and the Northrop T-38 Talon trainer (1959, widely used by NASA for astronaut training) [Ray Wagner 2000].

Brunolf Baade (German, 1904–1969) and Günther Bock (German, 1898–1970) designed jet aircraft such as Ju 287 bomber prototype (with forward-sweeping wings, first flown in 1944) at Junkers in Germany during the war, and others such as the Tu-95 "Bear" bomber (with back-swept wings, first flown in 1952) at Tupolev in the Soviet Union after the war. They also designed a civilian airliner version of the Tu-95, the Tupolev Tu-114. In those wartime and postwar projects, they collaborated with engine designer Ferdinand Brandner. See Fig. 9.108.

Sterling Pavelec, professor of aerospace history at the USAF Air Command and Staff College, explained the fundamental motivation and the ultimate impact of the German jet programs [Pavelec 2007, pp. 148, 154–156]:

> Even before the end of the war the Allies realized that the Germans had had an enormous impact on the evolution of military technology. In the final year of the war in Europe, the Germans led in nearly all fields of military technology, industrial capability, and theoretical knowledge. Some of the most impressive gains were in the fields of rocket technology (both manned and unmanned), turbojet aircraft, submarine technology[....] By the end of the war each of the major Allies—the British, the Americans, and the Soviets—were poised to capture German technology for future considerations. [...]
>
> Turbojets were devised, designed, and developed for their revolutionary potential. The Germans were the first—and in the end the best—in developing turbojet technology during the war for a number of reasons. Initially, turbojet development was a natural evolution of German academic predisposition. The advanced theoretical knowledge in the institutes of higher learning in Germany translated directly into conditions for developing nontraditional aircraft and power plants. The "shackles" of Versailles actually forced the Germans to start fresh without technological baggage. The young Doctor of Physics, Hans von Ohain, searching for "elegance" in flight, wanted to develop an alternative to the dirty, noisy, and rough propeller engine. Fortunately, for Germany, his ideas were accepted by an aviation industrialist who was searching for speed and efficiency. German aircraft designers were looking for revolutionary technology at the exact time it was becoming available. And that is not all; Dr. Franz, responsible for the development of the German axial-flow designs, also found the right time and climate for acceptance. His theories were proven correct; the Germans were the first to develop working, efficient axial-flow turbojets. Further, the Germans were devoted to increasingly higher theoretical advancement. In all forms of military hardware, the Germans were dedicated to developing the highest quality weapons by pursuing the boundaries of theoretical knowledge. [...]
>
> What held up the development of German turbojet aircraft was the lack of raw materials—chrome, nickel, and molybdenum—in Germany. Substitutes were found; the machines were built. [...] The Germans made do with what they had because they had to. There were no other alternatives. And still the Me 262—and later Ar 234 and He 162—were better than any Allied turbojet aircraft built during the same period.
>
> The longevity of the German turbojet program is evident in the impact on postwar military and civilian applications. The Americans virtually copied most German theoretical data and applied it directly to experimental programs. Further, German aeronautical engineers, designers, and technicians were brought to the United States to advance theoretical knowledge for their new bosses. The impact of German turbojet engineering was substantial.
>
> During World War II, the Americans and British were content to continue testing and with the development of conservative designs. Neither of the Western Allies felt the pressing need for turbojet aircraft throughout the war. [...]
>
> The Allies did not need turbojet aircraft to beat the Germans; the Germans needed their turbojet aircraft to have any hope of combatting the Allied bombers over Germany. The Germans did it first and did it right; and after the war, the Germans kept doing it for the powers that combined to defeat them in World War II.

For evidence that appears to demonstrate the development of even more advanced jet aircraft, including intercontinental jet bombers, in wartime Germany, see Appendix E.

Whether Whittle?

In the English-speaking world, the British engineer Frank Whittle is widely considered the inventor of the jet engine, or at the very least the co-inventor before or in parallel with the German engineers. For example, Oxford's *Biographical Dictionary of Scientists* says of Frank Whittle: "British engineer and inventor of the jet engine. The developments from his original designs were used first in the Gloster Meteor at the end of World War II. Direct descendents of these engines are now the sources of power for all kinds of military and civil aircraft" [Porter 1994, pp. 721–722]. The biographical dictionary never mentions Hans von Ohain or any other German-speaking inventors of jet engines and jet aircraft, apart from briefly remarking that "the Germans had produced the Messerschmitt Me 262 slightly earlier" than the British. The Oxford scholars do not even attempt to explain why all of the modern engines that are "now the sources of power for all kinds of military and civil aircraft" look absolutely nothing like Whittle's engines of which they are allegedly "direct descendents," yet instead bear an uncanny resemblance to the German engines.

Hill and Peterson's *Mechanics and Thermodynamics of Propulsion*, which has been the gold standard textbook of aerospace propulsion since its first edition in 1965, accurately summarized Whittle's jet milestones [Hill and Peterson 1991, p. 17]:

> [...A] company called Power Jets was formed in March 1936 that set to work on the development of a new engine while Whittle was still finishing his degree program. After enormous technical, financial, and bureaucratic difficulties, Whittle was able to run the engine for 20 minutes at 16,000 rpm on June 30, 1939, in a demonstration that at last convinced the authorities that his concept was valid and worthy of substantial support. On May 15, 1941, the first British jet aircraft, the Gloster Meteor, powered by the Whittle engine, flew from Cranwell in Lincolnshire.

After Whittle had demonstrated his engine, the older and very experienced British piston engine designer Frank Halford (1894–1955) stepped in and streamlined Whittle's engine as much as he could, leading to the Halford H-1 or de Havilland Goblin turbojet engine.

The United States actually produced a wartime jet, the Bell P-59 Airacomet, that used Whittle's jet engine design. Because of the engine's weight and inefficiency, the P-59 had a slower top speed and shorter range than even the piston-propeller P-51 Mustang. An improved U.S. jet, the Lockheed P-80 or F-80 Shooting Star, was also under development during the war but did not really come into much use until the postwar period.

Whereas all of Whittle's and Halford's engines and the earliest von Ohain prototype engines used centrifugal flow, most of the wartime German-produced engines employed axial flow and thus looked far more similar to jet engines used today.

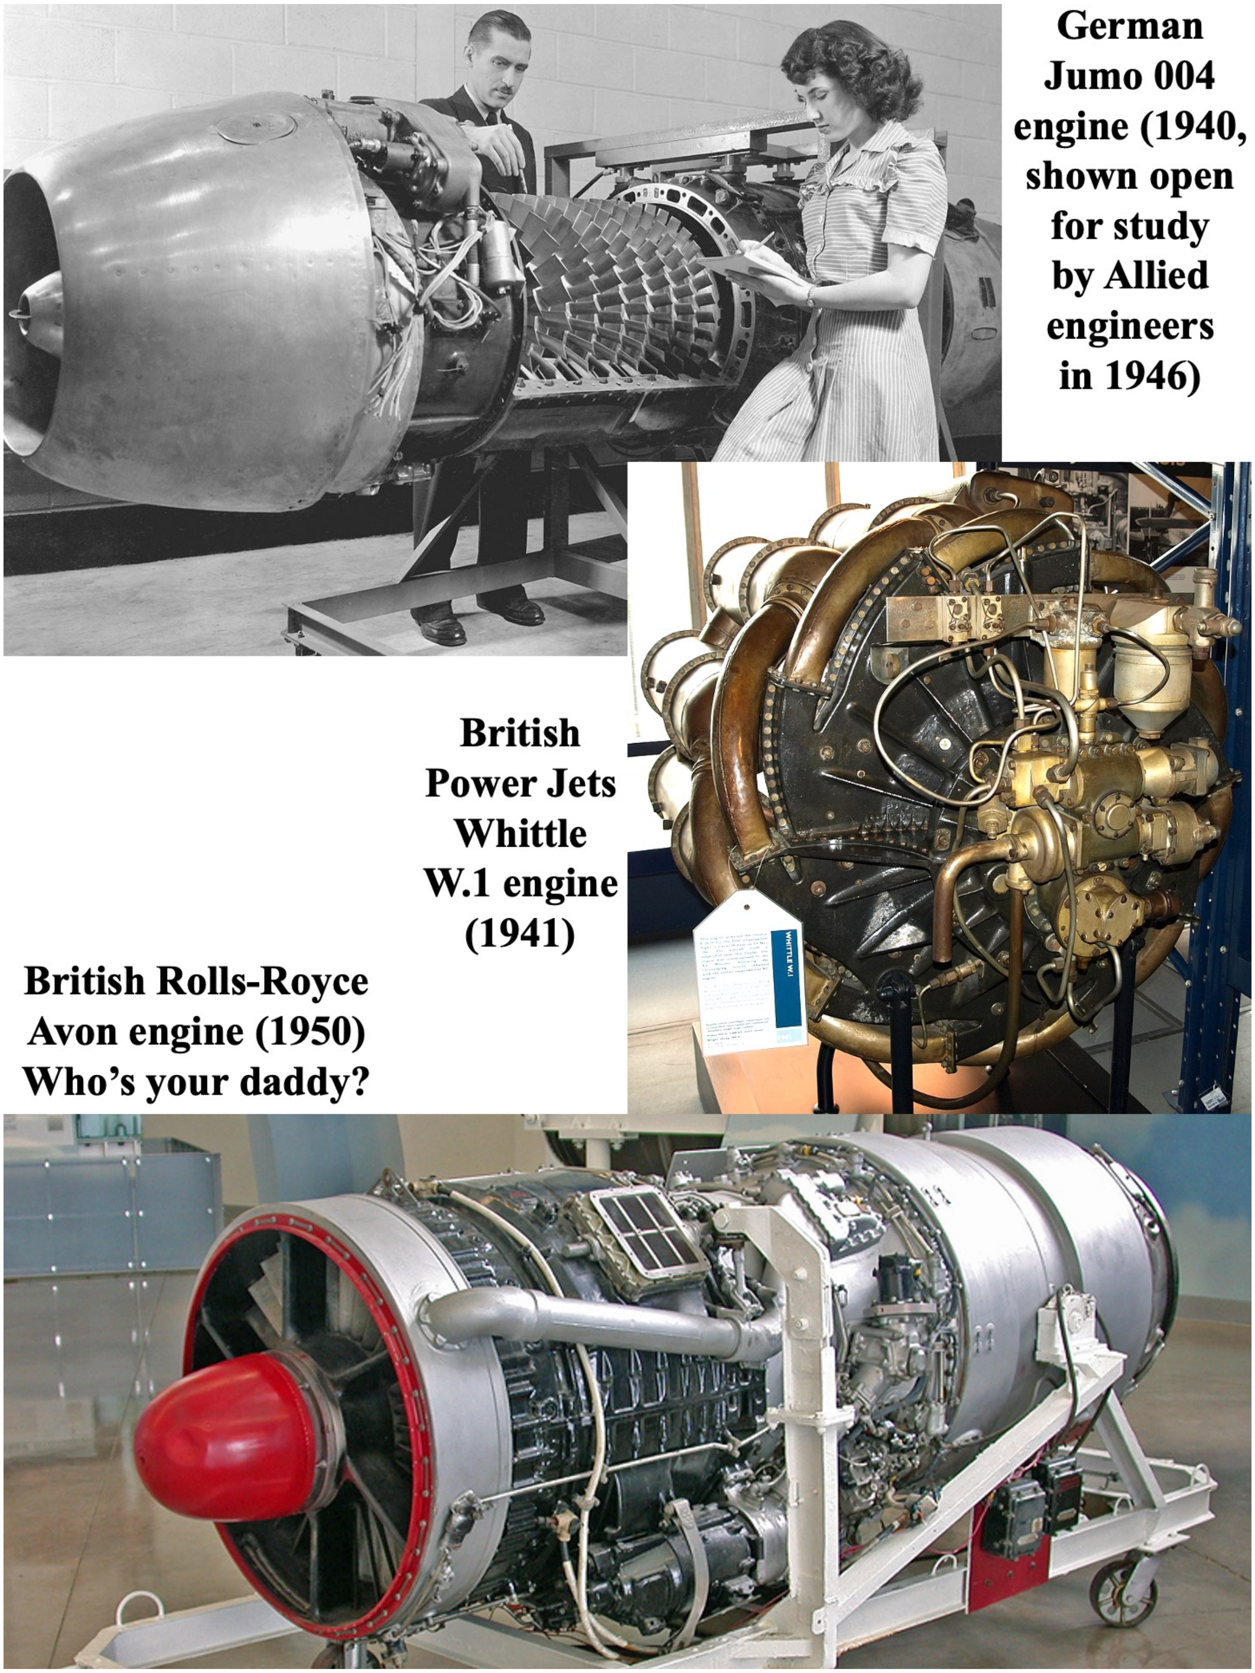
U.K. and U.S. jets produced during or soon after the war used the Whittle or Halford engine designs. However, the German jet engineers, designs, and prototypes were scooped up by Allied countries in 1945 and rapidly became the basis for turbojet, turbofan, turboprop, turboshaft, and ramjet engine designs that have been used worldwide ever since.

Kelly Johnson, the lead designer of the Lockheed P-80/F-80, compared wartime German and U.S./U.K. jets [Johnson and Smith 1989, pp. 95–96, 102–104]:

> The Air Corps commissioned use of the [Whittle jet] engine in the Bell P-59, originally designed as a propeller-driven airplane. When the jet-powered version flew in 1943, the performance was hardly better than that of the piston-powered P-38 and P-51. [...]
>
> The Germans by this time already had a number of jet-powered Me-262s in combat, and these planes were much faster than anything we had. They were well into the jet age while we were just starting. The Me-262 was a very good airplane, designed by Willy Messerschmitt, whose talent I respected. [...]
>
> The main concern turned out to be attack from the rear quadrant, where the German jets could overtake our aircraft, fly at any matching speed, and have considerably more time to aim and fire. [...]
>
> The war in Europe ended before the F-80 could be proved in combat there. But development, testing, and production continued.
>
> When the Air Corps team went to Germany after the war to inspect military capabilities, we at Lockheed were invited. [...]
>
> We found that the Germans had been flying the only axial flow jet engine in the world, fundamentally more efficient than the centrifugal compressors of the British jets because it was of simpler design. The flow went straight into the inlet and progressed in a straight line through the engine and out the exhaust. In centrifugal flow, the air goes in two sides of a rotor, flows perpendicular to the flight path of the airplane, enters the burner cans, then goes through the rest of the machine; so that it changes flow 90 degrees at least twice.

As explained by Kelly Johnson, Whittle's engine was very heavy, complex, and inefficient compared to the German designs, which were both earlier and more advanced. In the years following the war, even the British military and British companies abandoned Whittle's design and adopted the German designs (see for example Fig. 9.109).

It appears that the early U.K./U.S. jet engines were hampered not only by an inferior design, but also by a wartime research system that provided far less financial and political support than jet creators received in Germany. Moreover, during the war, the United States simply copied the British engine designs without even really trying to significantly innovate and improve upon them, as the German engineers were constantly doing with their own designs. U.S./U.K. support for jet innovation drastically increased after the war, once the performance of the German jets and the rising Cold War tensions with the Soviet Union became clear.



German Jumo 004 engine (1940, shown open for study by Allied engineers in 1946)

British Power Jets Whittle W.1 engine (1941)

British Rolls-Royce Avon engine (1950) Who's your daddy?

Figure 9.109: The British Rolls-Royce Avon turbojet engine began as a design project in 1945 and entered production in 1950. Does this postwar British engine look like wartime German engines such as the Jumo 004 or wartime British engines such as the Whittle W.1? Hint: What engines, information, and engine designers suddenly became available to British companies in 1945?

As shown in this section and summarized in Table 9.1, Whittle's British team was at least two years behind the German engineers at every step along the way in the development of jet engines and jet aircraft. In addition to these obvious differences in dates, the historical evidence shows that the German jet engines and jet aircraft were more sophisticated, more capable, and produced in greater numbers and greater varieties than their British counterparts.

If runners A and B are in a race, and runner B crosses the finish line two years after runner A, it would not be even remotely accurate or honest to say that runner B was the winner of the race, or even the co-winner. The evidence for the development of jets is clear, and historians must be clear as well. Frank Whittle was a talented engineer, but he was just one among countless engineers who worked on jet engines in the years following their invention and development by Hans von Ohain and the other German pioneers of the field.

The skies around the world today are filled with jet engines and jet aircraft that are directly descended from those created by the German engineers. Whittle's engines are evolutionary dead ends that can only be found in museums (Fig. 9.109).

Jet milestone	**German engineers**	**Whittle team**
First patent application	1925	1930
First proof-of-concept turbojet engine	1935	1938
First practical turbojet engine	1937	1939
First jet-powered flight	1939	1941
First twin-engine jet fighter	1941	1943

9.4 Parachutes and Ejection Seats

German-speaking scientists and engineers developed and demonstrated application-specific parachutes (Section 9.4.1) as well as ejection seats (Section 9.4.2) [Harsch 2006a, 2017, 2018; Hirschel et al. 2004; BIOS 466; FIAT 465; NavTecMisEu 247-45].

9.4.1 Parachutes

Hermann Lattemann (German, 1852–1894) and Katharina Paulus (German, 1868–1935) developed collapsible parachutes and backpack parachutes beginning in 1890 (Fig. 9.110). Lattemann died testing one of the parachutes in 1894, and Paulus continued to perfect the invention, producing a final product in 1910.

The parachute designers Gerhard Sedlmayr and Holger Hansen described the contributions of several other creators to parachute development; see Figs. 9.111–9.117 [Hirschel et al. 2004, pp. 309–315]:

> The second procedure—a stepwise deceleration—was developed by Waldemar Müller in 1924; here, a small auxiliary parachute is applied (free bag deployment), which, after being exposed to the flow, deploys and pulls the main parachute from the packing case and stretches it. The auxiliary parachute is connected to the apex of the main parachute by a short interconnecting cord. To improve the automatic procedures, the auxiliary parachute is, for instance, equipped with a steel spring so that it opens immediately after being released from the packing case. [...]
>
> Spherical canopies tend to oscillations if they are excited by small disturbances. At especially unfavourable circumstances, spherical canopies may even amplify these movements. To let air escape from the parachute canopy, an opening was placed at the apex of the parachute canopy, which resulted in a reduction of the pendulum-like oscillations. [...]
>
> Two essential brake parachutes originated which are still widely applied today. In 1933, Theodor W. Knacke started his theoretical and practical investigations to achieve the most effective deceleration of an aircraft in the air and during landing. In 1938, the development of the FIST [Flugtechnisches Institut der Technischen Hochschule Stuttgart] ribbon parachute was carried out by Georg Madelung and Theodor W. Knacke (first landing in 1939), and in 1941, the development of the guide-surface parachute by Helmut Heinrich. For the first time, parachutes became technically very efficient due to extensive theoretical research and numerous systematic experimental developments. [...]
>
> During 1933 and 1945, practical investigations of about 10,000 parachute drops were performed at the test center Rechlin from aircraft. More than half of these drops were filmed by high-speed cameras and documented. [...]
>
> In about 1937, the employees of the FIST (Georg Madelung, Theodor W. Knacke, Rudolf

> Isermann and Albert Keller) had the idea to build a parachute whose canopy consisted only of ribbons. [...] It still bears the name of the institute where it was developed, viz., "FIST ribbon parachute"; it is still being utilised today as recovery parachute, e.g., for reconnaissance drones, and as brake parachute for aircraft, landing space capsules and the Space Shuttle.
>
> After development work on a parachute canopy that consisted only of ribbons, the first trials started in 1938. [...]
>
> Under the supervision of Theodor W. Knacke, the FIST ribbon parachutes were further developed after 1946 in the USA, and various versions of the ribbon parachute resulted and were employed as brake and recovery parachutes. Probably the most attention-getting application of the further advanced ribbon parachute was the combination of several such chutes to a landing system for manned space flight up to the Apollo program of NASA. [...]
>
> The guide surface parachute of Helmut Heinrich was utilised in the unmanned spaceflight programs in conjunction with the Mars probe Viking and the Venus probe. [...]
>
> Based on the experiences with ribbon parachutes, the concept was again revised at FIST, and in 1940, Georg Pirzer and Friedrich Weinig started with the development of an entirely new ribbon parachute, the so-called "Great-circle Ribbon Parachute (Wako Canopy Parachute)". This design exhibits an up to now unprecedented performance.

After World War II, German designs for parachutes were widely adopted by other countries and used in a variety of aerospace projects, including the U.S. Apollo and Space Shuttle programs [Hirschel et al. 2004; BIOS 466; FIAT 465]. See Figs. 9.112–9.117.

9.4.2 Ejection Seats

Whereas pilots could simply grab a parachute and jump out of a malfunctioning lower-speed airplane, the advent of jet aircraft meant that a pilot attempting to bail out might be pinned inside the opened cockpit or blown into the tail of the aircraft by the very high-speed airflow. Thus higher flying speeds necessitated the development of a method to automatically, forcefully, and safely propel the pilot and parachute away from a malfunctioning aircraft.

At the Junkers aircraft company, Karl Arnhold (German, 19??–19??), Oscar Nissen (German, 19??–19??), Reinhold Preuschen (German, 19??–19??), and Otto Schwarz (German, 19??–19??) invented and patented aircraft ejection seats in 1938; see Figs. 9.118–9.119. In 1943, Erich Dietz (German, 19??–19??) filed a further patent application on improvements to ejection seats, as illustrated in Fig. 9.120.

Under the leadership of Ernst Heinkel (German, 1888–1958), engineers at the Heinkel aircraft company also developed ejection seats and made them standard equipment on a number of wartime aircraft. Figure 9.121 shows an ejection seat for a Heinkel 162 jet fighter, as well as an ejection seat in action in 1941.

After the war, the Junkers and Heinkel ejection seat technology was eagerly adopted by other countries, and such ejection seats have been used worldwide ever since.

In September 1945, R. P. Linstead and T. J. Betts, the British and American chairs of the Combined Intelligence Objectives Subcommittee (CIOS), listed a number of important German innovations for ejection seats and parachutes [AFHRA A5186 electronic version pp. 904–1026, Ch. 4, pp. 58–59]:

> The field of German aero-medical research was the subject of energetic investigation by United States and British specialists. The emergency oxygen bail-out system employed by the Luftwaffe in high altitude flying was regarded as of particular interest. This system permitted the use of the same oxygen mask by the pilot after leaving the plane. The device consisted of eight tubular bottles of oxygen connected in series by means of high pressure tubing. A three-way switch was employed which provided for normal supply, automatic disconnection prior to bail-out, and switching to the bail-out or emergency supply prior to parachute descent. As a result of this method, delays and complications arising from the necessity of changing masks prior to leaving the plane are eliminated.
>
> The Germans had developed ejection seats to permit pilots to leave high speed aircraft without injury. This equipment operated with a cordite charge which expelled the pilot from the cockpit so that his body was prevented from coming in contact with the tail surface or vertical fin of the plane.
>
> Much information was obtained concerning new types of parachutes developed by the enemy. These types included the non-pendulating parachute which was designed to equalize air turbulence on either side of the 'chute and thus avoid the possibility of accidental collapse and failures which characterize conventional types. Another development was the shock-free parachute consisting of a small pilot 'chute of air permeable construction to cushion the initial shock of release prior to opening of the main 'chute. A third type of parachute is known as the ribbon 'chute; this design provided for variable air orifices so that the rate of descent can be controlled. [...]
>
> Samples of froth clothing were obtained, i.e., flying clothing, treated with a chemical compound which generated heat by chemical reaction when placed in contact with cold water.

Junkers Flugzeug- und -Motorenwerke Akt.-Ges. in Dessau
Aus dem Innenraum eines Luftfahrzeuges durch einen Kraftspeicher entfernbarer,
mit einem Fallschirm ausgerüsteter Sitz

Patentiert im Deutschen Reich vom 23. Dezember 1938 an

Patenterteilung bekanntgemacht am 21. August 1941

Gemäß § 2 Abs. 1 der Verordnung vom 20. Juli 1940 ist die Erklärung abgegeben worden, daß sich der Schutz auf das Protektorat Böhmen und Mähren erstrecken soll.

Es ist insbesondere bei Flugversuchen vorteilhaft, Einrichtungen vorzusehen, um den Insassen des Luftfahrzeuges während des Fluges und besonders bei außergewöhnlichen Flugzuständen, insbesondere beim Trudeln, ein Verlassen des Innenraumes des Luftfahrzeuges zu ermöglichen. Zu diesem Zweck hat man bereits die Sitze für die Insassen an Führungsgliedern lösbar in der Weise festgelegt, daß nach Lösen der Befestigung der Stuhl mitsamt dem daraufsitzenden Insassen, sei es infolge Massenwirkung oder sei es unter Einwirkung eines besonderen Kraftspeichers, aus dem Innenraum herausbewegt wurde. Bei den bekannten Einrichtungen wird dann nach Verlassen des Luftfahrzeuges der am Sitz befestigte Fallschirm ausgelöst, und es gelangt der Insasse zusammen mit dem Sitz zum Erdboden. Die bekannten Einrichtungen haben aber den Nachteil, daß der Sitz in solcher Weise ausgestaltet sein muß, daß der Insasse den Landestoß mit den Beinen abfangen kann, wozu eine erhebliche Bewegungsfreiheit erforderlich ist. Diese Forderung ist aber mit der Gewährung eines ausreichenden Schutzes für den Insassen beim Verlassen des Flugzeuges durch den Sitz bei den bekannten Einrichtungen nicht vereinbar.

Gemäß der Erfindung ist nun die Ausgestaltung derart getroffen, daß der Insasse mit einem Fallschirm ausgerüstet und lösbar mit einem gehäuseartig gestalteten, aus dem Innenraum des Luftfahrzeuges bewegbaren Sitz verbunden ist, welcher seinerseits einen zweiten Fallschirm aufweist zur Beeinflussung der Fallbewegung des Gehäusesitzes. Die gehäuseartige Gestaltung des Sitzes gewährleistet dabei einen wirksamen Schutz für den Insassen in Fällen, in denen beim oder nach Verlassen des Innenraumes des Luftfahrzeuges Teile des Flugzeuges, z. B. das Leitwerk, in die Bewegungsbahn des Sitzes bzw. des Insassen geraten. Bei der erfindungsgemäßen Ausgestaltung kommt dann nicht der Insasse, sondern der gehäuseartige Sitz, welcher den Insassen zweckmäßig von drei Seiten umgibt, mit den Flugzeugteilen in Berührung. Auch erfolgt beim Verlassen des Flugzeuges die erste Abbremsung von dem hohen Flugstaudruck auf den Staudruck des freien Falles, während der Insasse noch fest mit seinem gehäuseartigen Sitz verbunden und dadurch gegen Verletzungen durch gewaltsame Körperbewegungen geschützt ist. Dies bedeutet gleichzeitig einen Schutz für den Insassenfallschirm gegen Überbeanspruchungen, da dieser erst bei verringerter Geschwindigkeit betätigt werden kann.

Ist nach der Trennung vom Luftfahrzeug die Gefahr der Berührung mit Flugzeugteilen behoben und der hohe Anfangsstaudruck durch den Eigenwiderstand des Stizes verringert, so wird der am Gehäuse angeordnete Fallschirm zur Entfaltung gebracht und anschließend die Verbindung des Insassen mit dem Gehäusesitz gelöst. Durch die Entfaltung des am Gehäuse angebrachten Fallschirms erfolgt die sichere Trennung des Gehäusesitzes von dem Insassen. Nach erfolgter Trennung löst dann der Insasse den an ihm befestigten Fallschirm aus und gelangt vom Sitz befreit in der üblichen Weise zum Erdboden.

Es wird demnach bei der erfindungsgemäßen Ausgestaltung einesteils ein Schutz für den Insassen nach Verlassen des Luftfahrzeuges und anderenteils eine ausreichende Bewegungsfreiheit zum Abfangen des Landestoßes gewährleistet, da der Insasse örtlich weit getrennt von dem Sitz zu Boden kommt.

Im weiteren Ausbau der Erfindung können noch Mittel vorgesehen sein, um im Falle des Versagens der Sitzschleudereinrichtung dem Insassen den Hinausstieg aus dem gehäuseartigen Sitz zu erleichtern, indem insbesondere der obere Teil des gehäuseartigen Sitzes aufklappbar oder entfernbar an den übrigen Teilen befestigt ist.

Der Erfindungsgegenstand ist in den Abbildungen in einem Ausführungsbeispiel veranschaulicht, und zwar zeigen

Abb. 1 den vorderen Teil eines Flugzeugrumpfes im Längsschnitt und den eingebauten,

711 045

in gesperrter Lage befindlichen gehäuseartigen Schleudersitz in Seitenansicht,

Abb. 2 den aus dem Flugzeug hinausgeschleuderten, vom Insassen befreiten Gehäusesitz am Fallschirm hängend; desgleichen den Insassen mit in Wirkung getretenem Fallschirm und das abstürzende Flugzeug mit entferntem Zellendach.

Der den Insassen zweckmäßig von drei Seiten umhüllende Gehäusesitz 1 ist in an sich bekannter Weise in einer Führung 2 lösbar derart festgelegt, daß nach Lösen der Befestigung durch Betätigen des Handhebels 3 unter voraufgehender Lösung und Entfernung des Zellendaches 4 der gehäuseartige Sitz 1 mitsamt dem daraufsitzenden Insassen unter Einwirkung eines besonderen Kraftspeichers, beispielsweise eines Gummizuges 5, aus dem Innenraum des Flugzeugrumpfes hinausbewegt wird. Der Insasse sitzt auf einem an seinem Körper mittels üblicher Gurte befestigten zusammengefalteten Fallschirm 6, der in Tätigkeit tritt, sobald der Insasse sich vom gehäuseartigen Sitz 1 befreit hat. Der Sitz 1 ist ebenfalls mit einem Fallschirm 7 versehen, der beim Lösen des Insassen vom Sitz 1 in Wirkung tritt, wobei der Insasse aus dem Gehäusestuhl 1 hinausfällt. Wie aus Abb. 2 ersichtlich, gelangen dann Insasse und Gehäusesitz getrennt zum Boden.

Um im Falle des Versagens der Sitzschleudereinrichtung dem Insassen das Hinaussteigen aus einem weitgehend geschlossenen gehäuseartigen Sitz zu ermöglichen, sind obere Teile des Gehäusesitzes, beispielsweise eine Kappe 9, entfernbar an den übrigen Teilen befestigt. In diesem Fall veranlaßt die Handhabe zum Lösen des Insassen vom Gehäusesitz zweckmäßig gleichzeitig das Lösen und Entfernen der Gehäusekappe 9. Die auf diese Weise vergrößerte Gehäuseöffnung dient dem Insassen dann zum Aussteigen.

PATENTANSPRÜCHE:

1. Aus dem Innenraum eines Luftfahrzeuges durch einen Kraftspeicher entfernbarer, mit einem Fallschirm ausgerüsteter Sitz, gekennzeichnet durch die Anwendung eines mit dem Insassen verbundenen besonderen Fallschirmes und eines gehäuseartig gestalteten Sitzes, mit welchem der Insasse lösbar verbunden ist.

2. Sitz nach Anspruch 1, dadurch gekennzeichnet, daß Teile, insbesondere der obere Teil, des gehäuseartigen Sitzes aufklappbar oder entfernbar an den übrigen Teilen befestigt sind.

KLASSE **62c** GRUPPE 23_{04}
J 5022 XI / 62 c

Dr.-Ing. Erich Dietz, Dessau
ist als Erfinder genannt worden

Junkers Flugzeug- und Motorenwerke AG., Dessau

Aus dem Innenraum eines Flugzeuges durch einen Kraftspeicher herausschleuderbarer Sitz

Patentiert im Gebiet der Bundesrepublik Deutschland vom 1. Juni 1943 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 11. Februar 1954
Patenterteilung bekanntgemacht am 5. August 1954

Die Erfindung bezieht sich auf Flugzeugsitze, die während des Fluges vermittels eines Kraftspeichers samt dem darauf sitzenden Besatzungsmitglied aus dem Flugzeuginnenraum herausschleuderbar sind. Solche Schleudersitze sind bekannt. Sie wurden bisher beim Einfliegen von Flugzeugen sowie bei Versuchsflügen mit besonders großer Absturzgefahr, z. B. bei Schwingungs- und Höchstgeschwindigkeitsflügen, benutzt, um der Flugzeugbesatzung die Möglichkeit zu geben, bei Gefahr aus dem Flugzeug rasch und ungehindert auszusteigen.

Mit dem Anwachsen der Fluggeschwindigkeiten hat sich das Bedürfnis herausgestellt, solche Schleudersitze nicht nur in Versuchsmaschinen, sondern auch serienmäßig als Normalsitze einzubauen, weil bei den durch die großen Fluggeschwindigkeiten bedingten außerordentlich hohen Staudrücken und Beschleunigungen ein Aussteigen der Besatzung mit eigener Kraft in der im Gefahrenfalle zur Verfügung stehenden kurzen Zeitspanne in der Regel nicht möglich ist. Der Befriedigung dieses Bedürfnisses steht jedoch entgegen, daß die bei den bekannten Schleudersitzen angewendeten Kraftspeicher in Form von gespannten Federn, Gummisträngen, Preßluft od. dgl. wegen der hierfür erforderlichen konstruktiven Einrichtungen verhältnismäßig viel freien Raum beanspruchen, der zwar in größeren Flugzeugen beispielsweise bei Schwingungsflügen zur Verfügung steht, solange die für den normalen Flugbetrieb erforderlichen Einbauten und Geräte noch fortgelassen sind, der aber in einer für ihren Einsatzzweck freigegebenen Maschine, insbesondere in kleineren Maschinen, beispielsweise in Jagdflugzeugen, nicht vorhanden ist. In solchen Maschinen sind daher Schleudersitze der bekannten Art unzweckmäßig.

Es wäre an und für sich denkbar, den Raumbedarf und Gewichtsaufwand solcher Schleudersitze

2 918 006

dadurch in tragbaren Grenzen zu halten, daß sie mit einer unter dem Sitz angebrachten Pulverladung als Schleuderkraftspeicher ausgerüstet werden. Dem steht jedoch entgegen, daß durch die schlagartige volle Entfaltung der Schleuderkraft das Besatzungsmitglied eine Beschleunigung erfahren würde, welcher der menschliche Organismus nicht gewachsen ist. Da außerdem eine Treibladung nach Art von Kartuschen nur schußartig wirkt, ist die Zeit der Krafteinwirkung äußerst gering gegenüber Kraftspeichern in Form von Federn, Preßluft od. dgl.

Die Erfindung beseitigt die erwähnten Mängel und Gefahrenquellen von Schleudersitzen der bekannten Art dadurch, daß als Kraftspeicher des in bekannter Weise längs flugzeugfester Führungen herausschleuderbaren Sitzes an dem Sitz eine oder mehrere Treibkammern mit Rückstoßdüsen nach dem Raketenprinzip angeordnet sind. Ein solcher Kraftspeicher ergibt eine weiche Rückstoßwirkung und ein allmähliches Anwachsen der Sitzbeschleunigung, was sich noch durch entsprechende Gestaltung der Düsen sowie durch die Dosierung und Zusammensetzung der Treibladung weitgehend beeinflussen läßt, so daß ein herausgeschleudertes Besatzungsmitglied selbst von vorübergehenden gesundheitlichen Störungen verschont bleibt. Da sich die Treibkraft der Rückstoßdüse so regeln läßt, daß sie ihren Höchstwert im Augenblick des Austretens des Sitzes in die freie Luftströmung erreicht und sodann noch kurze Zeit vorhält, ist es auch möglich, den Sitz genügend weit vom Flugzeug wegzuschleudern, so daß die Bedingungen für ein einwandfreies Katapultieren des Sitzes gewährleistet sind.

Ein weiterer, insbesondere vom militärischen Standpunkt aus bedeutsamer Vorteil eines erfindungsgemäßen Schleudersitzes besteht auch darin, daß die aus den Sitzrückstoßdüsen austretenden Stichflammen zur Erzeugung eines Brandherdes am Boden des Besatzungsraumes herangezogen werden können, dessen Verbreitung gegebenenfalls durch im Flugzeugboden eingebaute besondere Brandsätze noch begünstigt werden kann. Das von der Besatzung beim Absturz verlassene Flugzeug wird daher schon brennend am Boden aufschlagen und so rasch vernichtet, daß eine feindseitige Untersuchung auf technische Einzelheiten nicht mehr möglich ist. Sollte die Vernichtung des Flugzeuges durch Brandentfachung dagegen nicht erwünscht sein, so läßt sich die Brandwirkung der aus den Düsen austretenden Schwaden beispielsweise durch Klappen im Flugzeugboden vermeiden.

In weiterer Ausgestaltung der Erfindung wird die Anordnung der Rückstoßdüsen zum Gesamtschwerpunkt des belasteten Sitzes so getroffen, daß das beim Herausschleudern des Sitzes mit dem Besatzungsmitglied von der Luftströmung auf letztere ausgeübte Moment von dem aus der resultierenden Treibkraft herrührenden Moment bezüglich des Gesamtschwerpunktes im Hinblick auf die Lage oder Drehbewegung des Besatzungsmitgliedes vorbestimmbar ist.

Es ist selbstverständlich, daß der in der Schleuderrichtung des Sitzes befindliche Teil der Flugzeugbegrenzungswände vor oder beim Auslösen des Schleuderkraftspeichers, was beispielsweise auf elektrischem Wege über das Bordnetz und/oder eine Notbatterie erfolgen kann, abgeworfen wird. Hierfür geeignete Abwurfeinrichtungen sind bekannt. Es ist zweckmäßig, die benutzte Abwurfeinrichtung mit der Auslösung des Sitzkraftspeichers funktionsmäßig so zu kuppeln, daß beide durch einen einzigen Handgriff zur Wirkung gebracht werden können, was z. B. bei Absprengung des Daches durch eine gemeinsame elektrische Zündung erreicht werden kann.

Die Erfindung ist in der Zeichnung an Hand eines Ausführungsbeispiels in vereinfachter schematischer Darstellung näher erläutert. Es bedeutet 1 den im Besatzungsraum 2 eines kleinen, schnellen Flugzeuges, beispielsweise eines Jagdflugzeuges, angeordneten Führersitz, der mit Hilfe von Rollen 3 an seinem Unterteil sowie an seiner Rückenlehne in flugzeugfesten Führungen 4 derart beweglich geführt ist, daß ein Ecken und Hängenbleiben mit Sicherheit vermieden ist. An der Unterseite des Sitzes 1 ist ein Kraftspeicher in Form von Rückstoßdüsen 5 angebracht, durch deren Zündung der Sitz 1 samt dem darauf sitzenden Flugzeugführer im Sinne des eingezeichneten Pfeiles, wie gestrichelt dargestellt, aus dem Flugzeuginnern herausgeschleudert wird. Die oberhalb des Führersitzes befindliche Überdachung 6 ist zu diesem Zweck mit einer nicht dargestellten geeigneten Abwurfeinrichtung bekannter Art versehen, die unmittelbar vor oder bei der Zündung der Treibladung zur Wirkung gebracht wird.

PATENTANSPRÜCHE:

1. Aus dem Innenraum eines Flugzeuges durch einen Kraftspeicher längs flugzeugfester Führungen herausschleuderbarer Sitz, dadurch gekennzeichnet, daß als Kraftspeicher am Sitz eine oder mehrere Treibkammern mit nach dem Raketenprinzip arbeitenden Rückstoßdüsen angeordnet sind.

2. Schleudersitz nach Anspruch 1, gekennzeichnet durch eine derartige Anordnung der Treibkammern zum Gesamtschwerpunkt des belasteten Sitzes, daß das beim Herausschleudern des Sitzes mit dem Besatzungsmitglied von der Luftströmung auf letztere ausgeübte Moment von dem aus der resultierenden Treibkraft herrührenden Moment bezüglich des Gesamtschwerpunktes im Hinblick auf die Lage oder Drehbewegung des Besatzungsmitgliedes nach dem Verlassen des Flugzeuges vorbestimmbar ist.

3. Schleudersitz nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß der Sitzkraftspeicher zu benachbarten Flugzeugteilen oder besonderen Brandsätzen so angeordnet ist, daß diese Teile durch die aus den Speicherdüsen austretenden Flammen in Brand gesetzt werden.

9.5 Helicopters

German-speaking creators dominated the development of helicopters. They labored in the late nineteenth and early twentieth centuries to develop proto-helicopters, finally produced the world's first fully functional helicopters in 1936, mass-produced and fielded state-of-the-art helicopters during World War II, and played critical roles in the worldwide helicopter industry after the war.[10]

This section covers:

9.5.1. Proto-helicopters and autogyros

9.5.2. Henrich Focke's helicopter team

9.5.3. Anton Flettner's helicopter team

9.5.4. Friedrich von Doblhoff's helicopter team

9.5.5. Backpack helicopters

9.5.6. Electric helicopters

9.5.7. Transfer of helicopter technologies to other countries

9.5.1 Proto-Helicopters and Autogyros

The general idea of helicopters had been around since at least Leonardo da Vinci's designs for a cloth aerial screw, but the practical implementation of that idea was long hindered by two challenges: (1) making the helicopter powerful enough to support its own weight, and (2) making the helicopter stable enough that it would not rapidly spin out of control if it did lift off. With the advent of sufficiently powerful engines by the late nineteenth century, engineers worldwide began trying to build a functional helicopter.

Helicopters behave quite differently than other aircraft. In particular, a helicopter's main rotor may be regarded as a rotating wing that is always moving forward and thus can generate lift even if the helicopter itself is motionless. This confers on helicopters both their advantages, such as their ability to hover or even fly backwards, and their disadvantages, such as their high fuel consumption and limited speed relative to fixed-wing aircraft.

---

[10] See for example: Coats and Carbonel 2002; Hirschel et al. 2004; Jackson 2014; Johnston 1996; Leishman 2006; Myhra 2003; Nowarra 1990; NYT 1946-05-13 p. 4; BIOS Overall 8; CIOS XXXI-5; CIOS XXXI-11; FIAT 176; FIAT 177; FIAT 178; FIAT 604.

Figure 9.122 shows the airflow through a helicopter rotor. As shown in the upper half of the figure, the forces involved are less complex for purely vertical flight, and therefore it was less challenging for prototype helicopters to simply hover than for them to travel horizontally. To move forward or in another horizontal direction, a helicopter must tilt slightly toward the chosen direction, so that the rotor thrust has components causing both vertical lift and horizontal propulsion. Airflow to and from the rotor is then altered as shown in the lower half of the figure. The velocity of air far upstream from the rotor is inclined at an angle of attack α relative to the rotor.

Of course, a helicopter must have some method of counteracting the rotor torque so that the helicopter body will not spin wildly in the opposite direction from the rotor's rotation. Often a tail fin and tail rotor aimed to the side serve this purpose, though some helicopters simply avoid the problem by having two counter-rotating rotors on top.

The autogyro, another predecessor of true helicopters, should also be considered. This was an airplane with an unpowered, free-spinning rotor on top that was tilted slightly toward the rear of the craft. As the autogyro flew forward with its primary aircraft engine, the airflow spun the rotor, creating extra lift. This effect made the autogyro virtually stall proof at low forward speeds, although it could not hover completely motionless like a true helicopter with a powered rotor.

Almost all of the important early helicopter experimenters came from the greater German-speaking world. In general, prior to 1936, their early prototype helicopters could hover but not move forward without becoming unstable, and their closely related autogyro prototypes from the same period could move forward but not hover in place.

Early helicopter experimenters included:

- Hermann Ganswindt (German, 1856–1934) had many aerospace ideas that were far ahead of their time, designed a helicopter in 1884, and may have tested a prototype helicopter in 1901. See Fig. 9.123.

- Ján Bahýl' (Austro-Hungarian Slovak, 1856–1916) patented a helicopter design in 1895 and briefly flew a prototype in 1905, as shown in Fig. 9.124.

- István Petróczy (Hungarian, 1874–1957), Theodore von Kármán (Hugarian, 1881–1963), and Vilém Žurovec (Czech, 1883–1935) created proto-helicopters such as the electric-powered PKZ-1 (1918) and gasoline-powered PKZ-2 (1918). See Fig. 9.125.

- Emil(e) Berliner (German, 1851–1929) moved to the United States, where he built and tested prototype helicopters and autogyros 1909–1929, as illustrated in Fig. 9.126. Toward the end of his life, he was also assisted by one of his sons, Henry Berliner (1895–1970).

- Engelbert Zaschka (German, 1895–1955) built and patented a prototype helicopter, which he dubbed Rotary Wing, in 1927. See Fig. 9.127.

- Albert Gillis von Baumhauer (Dutch, 1891–1939) experimented with a helicopter prototype 1924–1930 (Fig. 9.128) but never could overcome its instability problems, which ultimately destroyed the prototype.

- In the 1920s and early 1930s, Oskár von Asboth (Hungarian, 1891–1960) built several helicopter prototypes that could hover but that became unstable when they tried to move. See Fig. 9.129.

- Raoul Hafner (Austrian, 1905–1980) built prototype autogyros in the 1920s and 1930s, first in Austria and then in the United Kingdom. While in Austria, he collaborated with Bruno Nagler (Austrian, 1901–1979) to create proto-helicopters such as the Hafner-Nagler R.I Revoplane (1929), shown in Fig. 9.130.

- Walter Rieseler (German, 1890–1937) built prototype autogyros and helicopters in the 1920s and 1930s but died in 1937, just as helicopter technology was finally coming to fruition. See Fig. 9.131.

In the 1930s and early 1940s, at least three German-speaking teams—led by Henrich Focke, Anton Flettner, and Friedrich von Doblhoff—finally developed fully functional large helicopters that were able to both hover and move in a stable fashion.

9.5.2 Henrich Focke's Helicopter Team

In 1936, Henrich Focke (German, 1890–1979) created the Focke-Wulf Fw 61, the world's first fully functional helicopter, as shown in Fig. 9.132.

His engineering team included:

- Harry Duda (German, 19??–19??, mechanical design and manufacturing)
- Hans Gerd Eyting (German, 19??–19??, mechanical design and manufacturing)
- Reinhold Gensel (German, 19??–19??, design)
- ?? Helme (German, 19??–19??, mechanical design and control)
- K. Jäckel (German, 19??–19??, aerodynamics and stability)
- Walter Just (German, 1909–1980, aerodynamics and stability)
- Paul Klages (German, 1899–1959, mechanical design and overall development)
- Heinrich Papenhausen (German, 19??–19??, statics and material testing)
- Friedrich Schaper (German, 19??–19??, statics)
- Erich Schweym (German, 19??–19??, aerodynamics and stability)
- Herbert Spranger (German, 19??–19??, development and aerodynamics)
- Enno Springmann (German, 19??–19??, mechanical design)

The Fw 61's development also involved several test pilots, the first of whom was Ewald Rohlfs (German, 1911–1984). In February 1938, the famous pilot Hanna Reitsch (German, 1912–1979, Fig. 9.217) demonstrated the Fw 61 in a crowded indoor sports arena in Berlin every day for three weeks to show the public how controllable and reliable the newly invented helicopter was (Fig. 9.132).

The Focke team subsequently developed other helicopters such as the Focke-Achgelis Fa 223 Drache (Dragon) twin-rotor cargo helicopter (Fig. 9.133). The Fa 223 was first flown in 1940, went into series production, and was used in the war.

In 1942, they designed the larger Focke-Achgelis Fa 284 heavy cargo helicopter (Fig. 9.134) and the four-rotor Fa 325 Krabbe heavy cargo helicopter (Fig. 9.135), but Allied attacks halted construction on those projects.

Focke's team produced a prototype of the Fa 269 tilt-rotor VTOL (vertical takeoff and landing) aircraft that was actually rather similar to the modern U.S. V-22 Osprey (Fig. 9.136). However, it was destroyed by Allied bombing in 1944.

In 1942, Focke and his team developed the novel and useful Focke-Achgelis Fa 330 Bachstelze rotor kite, which could be deployed and towed by a submarine (via a 150-meter cable) as an aerial lookout. (Fig. 9.137).

In 1939, Focke's team designed the Rochen, a winged VTOL aircraft with counter-rotating rotors in a ducted fan (Fig. 9.138). Focke's design lives on in examples such as the Sikorsky Cypher II or Dragon Warrior drone (2000).

They also designed the even more radical Focke-Wulf Triebflügel jet-powered rotary-wing VTOL aircraft (Figs. 9.139–9.140). It had wing-tip ramjets and was designed to take off and land vertically but fly horizontally. The Triebflügel was designed in 1944; it is unclear how far experimental work got by the end of the war.

Closely related to the Focke-Wulf Triebflügel were the Heinkel Wespe and Heinkel Lerche (Fig. 9.141 shows the Lerche; the Wespe was highly similar but somewhat smaller), which were also designed but apparently not completed during the war. After the war, the Triebflügel and Lerche/Wespe designs (and perhaps some of the engineers who worked on them?) directly inspired similar projects such as the Lockheed XFV Salmon (1954) and Convair XFY Pogo (1954). While the Lockheed XFV could fly vertically or horizontally but could not make the transition between those two modes, the Convair XFY was completely successful at demonstrating the feasibility of taking off vertically, transitioning from vertical to horizontal flight, flying horizontally, transitioning from horizontal to vertical flight, and landing vertically.

As shown in Fig. 9.142, the wartime German Lerche/Wespe- and Triebflügel-type designs (for aircraft that could take off and land on their tails but pitch over by 90^o to fly horizontally) still live on in modern unmanned aerial vehicles (UAVs) such as the University of Kansas XQ-138 drone and the Martin UAV V-BAT drone.

After the war, Henrich Focke and other members of his team produced helicopters for France, the Netherlands, Brazil, and West Germany.

9.5.3 Anton Flettner's Helicopter Team

As shown in Fig. 9.143, Anton Flettner (German, 1885-1961) also demonstrated his own fully functional helicopter, the Flettner Fl 185, in 1936 very soon after Focke. Previously Flettner had invented battlefield robots (p. 1208) and rotor ships (p. 1484).

In addition to several test pilots, his engineering team included:

- Emil Arnold (German, 19??–19??, chief designer)
- Willi Deilitz (German, 19??–19??, test facilities)
- Heinz Gundlach (German, 19??–19??, designer)
- Kurt Hohenemser (German, 1906–2001, aerodynamics and stability)
- ?? Küchler (German, 19??–19??, transmissions)
- Oskar Nagel (German, 19??–19??, project designer)
- Xaver Schleicher (German, 19??–19??, flight mechanics)
- Joseph Schmidt (German, 19??–19??, flight-test engineer)
- Gerhard Siegel (German, 19??–19??, statics)
- Gerhard Sissingh (German, 1907–2002, aerodynamics)

Flettner's team went on to create other helicopters such as the much more advanced Fl 282 Kolibri (Humming Bird) reconnaissance helicopter. The Fl 282 was first flown in 1941, went into series production, and was used in the war. See Fig. 9.144.

Flettner and his team also developed the Fl 265 helicopter/autogyro (1938), the improved Fl 285 reconnaissance helicopter (1944, Fig. 9.145 top), and the large Fl 339 passenger/cargo helicopter prototype, which apparently was not completed before the end of the war (Fig. 9.145 bottom).

After the war, Flettner, Hohenemser, and Sissingh produced helicopters in the United States.

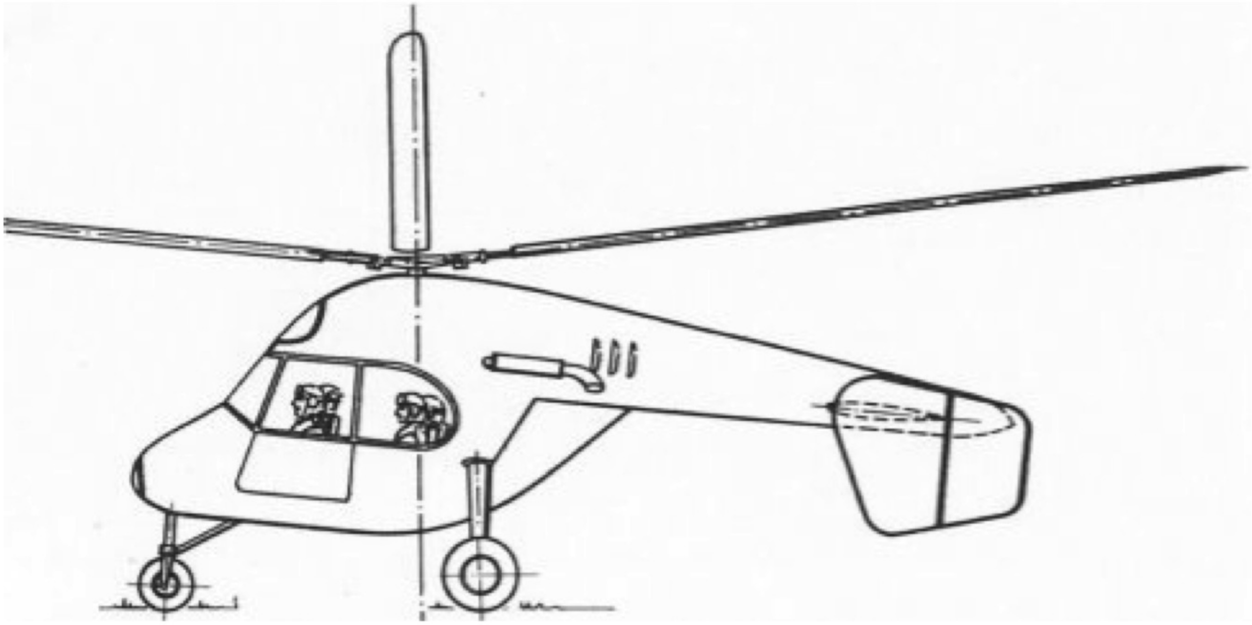

Figure 9.145: By the end of the war, Flettner's team had produced the improved Flettner Fl 285 reconnaissance helicopter and was building the much larger Fl 339 passenger/cargo helicopter.

9.5.4 Friedrich von Doblhoff's Helicopter Team

In 1943, Friedrich von Doblhoff (Austrian, 1916–2000) demonstrated the prototype WNF 342 submarine-launched helicopter, which featured a rotor that was directly powered by small jet engines at the rotor tips; see Fig. 9.146.

Some of the other members of his engineering team were:

- Alexander Czernin (Austrian, 19??–19??, mechanical design)
- Theodor Laufer (Austrian, 1875–1951, aerodynamics and stability)
- Kurt Löffler (Austrian, 19??–19??, detailed design)
- August Stepan (Austrian, 1915–2003, structural design)
- M. Vordren (Austrian, 19??–19??, detailed design)

After the war, von Doblhoff developed helicopters in the United States, Czernin and Stepan built helicopters in the United Kingdom, Stepan later developed helicopters in West Germany (including the revolutionary MBB Bo 105), and Laufer built helicopters in France. Several of the postwar helicopters designed by former von Doblhoff team members were propelled by the same tip-jet rotor approach as the wartime WNF 342, including the McDonnell XV-1 military helicopter, Fairey Jet Gyrodyne test prototype, and Fairey Rotodyne passenger vehicle (Fig. 9.147).

9.5.5 Backpack Helicopters

Special mention should go to three innovators who created and successfully demonstrated prototype "backpack" helicopters during the war:

- Paul Baumgärtl (Austrian, 1920–2012) produced and tested a series of one-person helicopters that he called Heliofly (Fig. 9.148). Baumgärtl's prototypes included Heliofly I (1941), which attached directly to the back of the pilot, and Heliofly III (1943), which was essentially a flying chair for the pilot.
- Beginning in 1940, Bruno Nagler (Austrian, 1901–1979) and Franz Rolz (Austrian, 19??–19??) demonstrated the NR 54 and NR 55 prototype helicopters, which could be folded up and carried as a backpack, or unfolded into a helicopter for use by a seated pilot (Fig. 9.149). After the war, Nagler moved to the United States, where he continued to develop and demonstrate portable helicopters such as the strap-on backpack Heliglider (1952).

9.5.6 Electric Helicopters

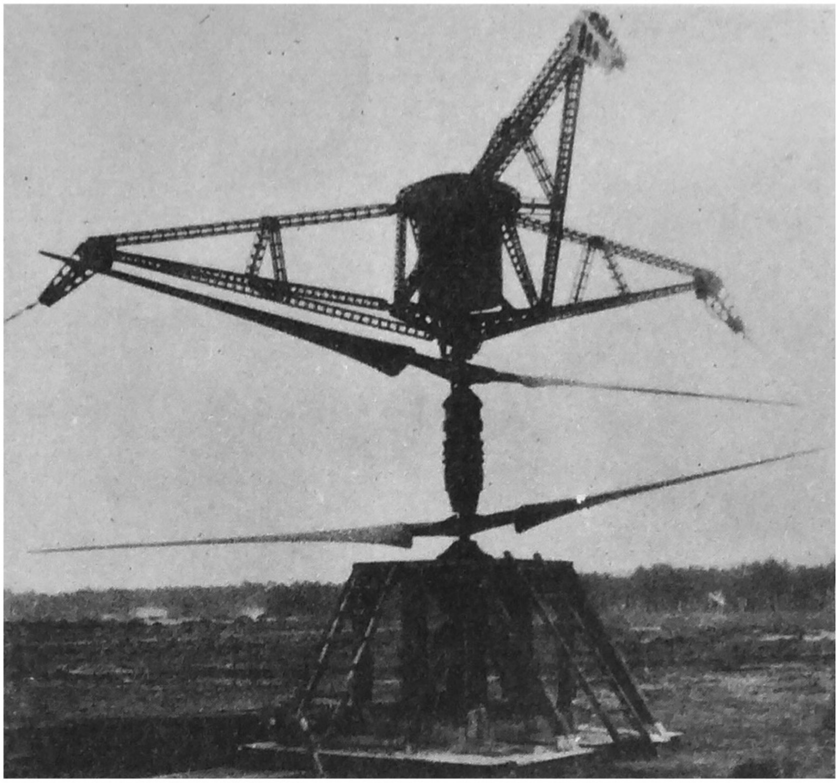
The PKZ-1 proto-helicopter that was built by István Petróczy, Theodore von Kármán, and Vilém Žurovec (Fig. 9.125) in 1918 demonstrated the potential of electric-powered helicopters.

While most helicopters focused on fuel-burning engines of various types, R. Schmidt (German, ??–??) and G. Kirchberg (German?, ??–??), engineers working at the electrical equipment company AEG, continued the development of electric helicopters. Beginning in 1933, they built and demonstrated a series of increasingly sophisticated electric helicopters that could be launched from a truck and that remained tethered by power cables to a ground-based electric generator. Figure 9.150 shows the final (1945) version of the helicopter, in which the hovering vehicle and its attached cables could function as a large radio antenna. By sending the helicopter aloft from the truck, the system could act as a portable radio tower [FIAT 604].

Electric helicopter/quad-copter drones are now quite common, and they are deeply indebted to these first electric helicopters.

R. Schmidt
(19??–19??)

Electric helicopter launched from a truck and connected via power cables to a ground-based generator (1933–1945)



G. Kirchberg
(19??–19??)

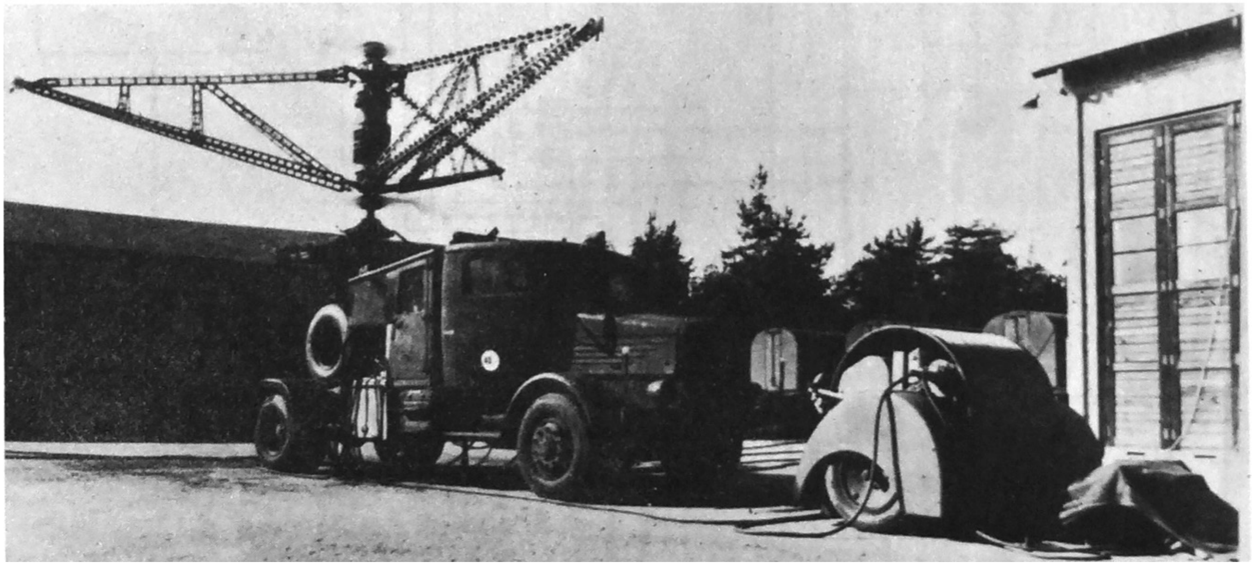


Figure 9.150: R. Schmidt and G. Kirchberg developed an electric helicopter launched from a truck and connected via power cables to a ground-based generator. The helicopter and its attached cables were designed to function as a giant radio antenna, effectively making the whole system a portable radio tower [FIAT 604].

9.5.7 Transfer of Helicopter Technologies to Other Countries

Outside the German-speaking world, the closest competitor in helicopter development was probably Igor Sikorski (1889–1972), a Russian engineer who emigrated to the United States. By May 1940, he had created a prototype helicopter (VS-300) that could hover but became unstable if it tried to move forward, the same problem that had plagued German prototypes of earlier decades. A version that could both hover and move forward, the R-4, was first demonstrated in 1942, six years after the first fully functional Focke and Flettner helicopters, and presumably after the details of the various Focke and Flettner designs would have become available in the West to aid Sikorski's experiments. However, the early R-4 versions still had a number of issues, and in order to resolve those, the R-4 design had to go through a series of further modifications, prototypes, and tests for two more years. The first actually useful versions of R-4 helicopters were finally fielded in the war in small numbers by the United States in 1944 and the United Kingdom in 1945, 4–5 years after Germany's first fully operational helicopters had been mass-produced and deployed.

Not only were the German helicopters produced many years earlier than U.S. helicopters, but they were technically superior, according to U.S. officials. Even compared to U.S.-built helicopters of 1946, the *New York Times* practically gushed about the performance of the 1940 Fa 223 Drache (Dragon) twin-rotor cargo helicopter [NYT 1946-05-13 p. 4]:

> The Germans built ten big helicopters able to climb eighteen feet a second with ten passengers aboard and a full load of fuel before the Allies bombed out the manufacturing plant at Bremen, the Commerce Department disclosed tonight.
>
> The Department made available a report giving specifications of the helicopter which has many unusual features, including a different method for suspending the engine in the craft, which can fly up, down, forward, backward, or sideways.

In the United States after the war, German-speaking helicopter engineers collaborated with German-speaking turbojet engine designers such as Anselm Franz to produce more energy-efficient helicopters powered by turboshaft engines such as the Lycoming T53 and T55 engines (see p. 1740). Such turboshaft-powered helicopters are still the standard helicopter design. By the Korean War, helicopters were routinely used for medical evacuations, and by the Vietnam War, helicopters were the preferred platform for virtually all aerial tasks except bombing.

As already noted, several key engineers from the original Focke, Flettner, and von Doblhoff helicopter teams also developed helicopters in the United Kingdom, France, and other countries after the war. The Soviet Union was late to field fully functional helicopters, but (apparently) with the help of captured German designs and engineers, it began serial production of the small Mi-1 Hare helicopter in 1950, followed by more advanced helicopters in the 1950s and beyond.

9.6 Small Missiles and Smart Bombs

German-speaking engineers developed precision-guided missiles and smart bombs that were the direct forerunners of modern guided weapons.[11] The wartime (Section 9.6.1) and postwar (Section 9.6.2) missile programs were so numerous and so large, and employed so many German-speaking engineers, that only a few examples are mentioned here.

9.6.1 Wartime Missiles and Smart Bombs

While many of the most important and best known advances in missiles and smart bombs occurred just before and during World War II, some remarkable work was actually conducted just before and during World War I [Everett 2015; Trenkle 1987]. As shown in Fig. 9.151, Siemens-Halske engineers developed and successfully demonstrated the first wire-guided glide bombs in 1914. Siemens-Halske also worked with Mannesmann-Mulag to create and demonstrate the even more ambitious Fledermaus radio-controlled explosive airplane in 1916. Those nearly forgotten programs deserve greater recognition and more archival research by military and aerospace historians.

Paul Schmidt (German, 1898–1976, designer of the Argus As 014 pulsejet engine), Fritz Gosslau (German, 1898–1965, missile designer), and Robert Lusser (German, 1899–1969, missile designer) led teams that created the V-1 or Fieseler Fi 103 cruise missile, first flown in 1942, which was powered by a novel pulsejet engine (Figs. 9.101 and 9.152).[12] During the war, versions of the V-1 cruise missile that were piloted and/or air-launched were also produced and demonstrated (Fig. 9.153). After the war, Schmidt, Gosslau, and Lusser worked for the United States to produce missiles and other technologies.

As shown in Fig. 9.154, Herbert Wagner (Austrian, 1900–1982) led a team that created precision-guided weapons such as the Henschel Hs 293 smart bomb, guided by a miniaturized onboard camera and first demonstrated in 1942, and the Henschel Hs 117 Schmetterling (Butterfly) surface-to-air and air-to-air missile, also guided by a miniaturized onboard camera and first demonstrated in 1944. The miniaturized camera and television system are shown on pp. 1008–1010. Wagner was an extremely versatile and prolific inventor. In the 1930s, he created some of the first jet engines, and his designs strongly influenced subsequent jet engine developers (pp. 1734–1738). He also worked on German nuclear weapons programs during the war (p. 4165). After the war, Wagner developed a wide range of guided missiles and smart bombs in the United States.

---

Max Kramer (German, 1903–1986) created precision-guided weapons such as the Ruhrstahl SD 1400 X (Fritz X) radio-guided or wire-guided (to avoid radio jamming) smart bomb, first operational in 1943, and the Ruhrstahl X-4 air-to-air guided missile in 1944, as well as the Ruhrstahl X-7 anti-tank missile; see Fig. 9.155. After the war, Kramer worked in the United States to develop additional missiles and aircraft and to reduce drag on submarines. Kramer's wartime missiles also had a profound influence on the development of postwar missiles in other countries; for example, the French SS.10 anti-tank missile was directly based on the Ruhrstahl X-7.

Note that Wagner's and Kramer's smart bombs were developed and deployed nearly a half century before U.S. smart bombs directly based on that technology were first widely publicized in the 1990 Gulf War.

Heinrich Klein (German, 19??–19??) led the Rheinmetall-Borsig team that created the Rheintochter two-stage, radio-guided, surface-to-air missile, which was first demonstrated in 1943 (p. 1912). Klein's team also created the larger Rheinbote four-stage missile, first launched in 1943 (p. 1913) [Klein 1977; Margry 2001; Mills 2020, 2022]. In fact, according to a 1947 French military document, during the war Klein was even personally involved in "the construction of flying rockets... capable of crossing the Atlantic in 40 minutes" (p. 5452).

Ludwig Roth (German, 1909–1967) led the team at Peenemünde that developed the Wasserfall surface-to-air missile, which was essentially a miniature version of the A-4 (V-2) rocket. See Fig. 9.156. The Wasserfall was first demonstrated in 1944, and was designed to be either radio- or radar-guided. After the war, Roth moved to the United States to continue developing missiles and rockets. The Wasserfall was copied and became the Hermes series of U.S. missiles, and its technologies were incorporated into other postwar missiles [Mills 2020, 2022].

Messerschmitt's Oberbayerische Forschungsanstalt in Oberammergau developed the Enzian surface-to-air missile, which was first demonstrated in 1944. See Fig. 9.157. It was designed to use either radio guidance or infrared homing to find its target.

A team led by Klaus Scheufelen (German, 1913–2008) developed the Taifun surface-to-air missile, which was first demonstrated in January 1945 (Fig. 9.158). Scheufelen continued to develop missiles and rockets in the United States after the war.

U.S. Army Air Forces Colonel (later General) Donald Putt, who recruited many of these German-speaking engineers at the end of World War II and supervised their postwar work in the United States, gave an unclassified public overview of their wartime accomplishments in 1946 [Putt 1946b]:

> The Germans were preparing rocket surprises for the whole world in general and England in particular, which would have, it is believed, changed the course of the war if the invasion had been postponed for so short a time as six months. Many of Germany's research laboratories and several large commercial firms concentrated on this field of endeavor. This tremendous effort resulted in 138 guided missiles and assorted devices, including their modifications. [...]
>
> The stupendous effort in basic research expended by the Germans in the guided missile field was designed to cover the complete field of potentialities for such weapons. The losses incurred in Germany by heavy bomber raids can in no way be charged to lack

of preliminary research on missiles. Weapons of this category were divided into the following classifications:

A. Ground to air.

B. Air to air.

C. Air to ground.

D. Ground to ground.

E. Underwater to underwater.

F. Underwater to ground.

G. Underwater to air.

Moreover, every known type of remote control and fusing means was exploited. These included radio control, wire control, radar, continuous wave, acoustics, infrared, light beams, and magnetics.

Likewise, all methods of employing jet propulsion for subsonic and supersonic speeds were exploited.

In all, it was estimated that one-third of the aerodynamics research in Germany was devoted to problems of guided missiles. [...]

Some of the classes of German missiles based on intended use are:

A. The Beethoven [...] was an air-to-ground missile. [...]

B. The Enzian [...] was a ground-to-air missile. [...]

C. The Wasserfall was a ground-to-air missile. [...]

D. The X-4 was an air-to-air missile. [...]

E. The Fitz X [...] was an air-to-ground missile. This German bomb was released from aircraft flying at a minimum altitude of 22,000 ft. It was gyrostabilized and visibly guided into the target by radio. The Fritz X was ready for operational use in January, 1943, and was first employed successfully against our shipping and assault forces at Salerno. The warhead on this bomb was armor-piercing and carried a charge of 2530 lb of standard explosive.

F. The Hs-298 [...] was an air-to-air missile. [...]

G. The Hs-117 [...] was a ground-to-air missile. It was named Schmetterling or butterfly, and was a rocket-propelled, radio-controlled missile to be launched from

> the ground against bomber formations. It accelerated to a speed of 560 mph, and was steadied in flight by a pendulum device. The take-off rocket burned out and were jettisoned; the main propulsion unit then drove the missile until it was detonated by a proximity fuse. Large-scale production began January, 1945, in an underground factory in Nordhausen.
>
> H. The Rheintochter [...] was a ground-to-air missile. It was a rocket-propelled anti-aircraft weapon and was controlled in flight by radio. It traveled at a speed of 1100 mph and carried an explosive charge of 330 lb, equipped with a proximity fuse, to a ceiling of 48,000 ft. The starting rocket, attached to the base, was blown off after combustion was completed. Development did not go beyond the test firing stage, but experiments were still being conducted as late as February, 1945. The code name Rheintochter means daughter of the Rhine.
>
> I. The FZG-76 [...] was a ground-to-ground missile. [...]
>
> In conclusion may I state that the Germans in the guided missile field were 10 years in advance of similar American development.

As just one more example of countless statements from the U.S. military about the effectiveness of German missiles, consider: Says Nazis Had New Rocket, *New York Times* 1946-01-18 p. 6:

> Germany developed a new rocket a month before V-E Day which proved so accurate that it almost ended Allied bombing attacks, Col. Leslie Simon, director of the Aberdeen Ballistics Research Laboratory, said today before 300 scientists and engineers meeting here. He declared that the weapon enabled the Germans to bring down our bombers "almost at will." The new rockets were mounted in groups of twenty-four on fast German interceptor planes.

9.6.2 Postwar Missiles and Smart Bombs

The wartime missiles shown in this section are among the better-known German technological accomplishments. What is less well known is that those wartime missiles were not an engineering dead end. The scientists, engineers, prototypes, designs, methods, and experience from those programs were all used to create a wide variety of missiles that have been used around the world ever since [Mills 2020, 2022].

Figures 9.160–9.162 show just one example—some of the German-speaking scientists who developed U.S. missiles at the Naval Air Missile Test Center, Point Mugu, California. They included:

Alexis Dember (German, 1912–2002)

Willy Fiedler (German, 1908–1998)

Ernst Friedrich (German, 19??–19??)

Wilfried Hell (German, 1914–2010)

Werner Hohenner (German, 1907–2000)

Hans Hollmann (German, 1899–1960)

Edgar Kutzscher (German, 1906–19??)

Reinhard Lahde (German, 1908–1999)

Johann Ludloff (German, 19??–19??)

Robert Lusser (German, 1899–1969)

Otto Schwede (German, 1912–2005)

Theodore Sturm (German, 19??–19??)

Herbert Wagner (Austrian, 1900–1982)

Etc.

These and other German-speaking scientists were responsible for the postwar development of cruise missiles in the United States and other countries. As a starting point, the V-1 was directly copied and deployed by the United States, renamed as the Loon missile [p. 1896; Quigg 2014]. Using captured German prototypes, factories, and engineers, the Soviet Union also copied and deployed the V-1, designating it as the 10Kh missile. The German-speaking scientists then created a long line of more advanced cruise missiles, ranging from late 1940s–1950s examples (e.g., U.S. SM-62 Snark, SM-64 Navaho, MGM-1 Matador, SSM-N-6 Rigel, and SSM-N-8 Regulus; Soviet P-5 Pyatyorka) to modern cruise missiles (e.g., U.S. BGM-109 Tomahawk and AGM-86 Air-Launched Cruise Missile (ALCM); Russian Kh-55 and Kh-101).

As another example of direct technology transfer from the German-speaking world, the Bell GAM-63 RASCAL (RAdar SCAnning Link) air-launched cruise missile was designed by Walter Dornberger (German, 1895–1980, Fig. 9.223) in 1946 and first launched in 1953; see Fig. 9.164. Essentially it was a German-derived liquid propellant rocket that was intermediate in size between the Wasserfall (p. 1844) and A-4/V-2 (p. 1860) and was deployed like the air-launched V-1 (p. 1841). There was also a British version of the RASCAL, the Avro Blue Steel (Fig. 9.165), which was deployed in 1963. (Dornberger had worked for the British immediately after the war, before going to the United States.)

The German-speaking scientists also developed a wide range of other postwar missile types, including for example:

- AGM-12 Bullpup air-to-ground missile
- SSM-A-23 Dart anti-tank missile
- AIM-4 Falcon air-to-air missile (p. 1155)
- AGM-84/RGM-84/UGM-84 Harpoon anti-ship missile
- MIM-23 Hawk surface-to-air missile
- AAM-N-4 Oriole air-to-air missile
- MGM-51 Shillelagh anti-tank missile
- AIM-9 Sidewinder air-to-air missile (p. 1155)
- AIM-7 Sparrow air-to-air missile

Furthermore, German-speaking scientists and engineers created a wide variety of missile guidance, tracking, and homing systems during the war, and continued to develop those technologies in other countries after the war. For infrared and heat-seeking targeting systems for missiles, see pp. 1131–1155. For radio and acoustic proximity fuses and homing devices, see pp. 1254–1258, 5411.

For German-speaking contributions to larger rockets, see Sections 9.7–9.8 and Appendix E.

Nazi Weapon Experts Now Aiding Navy

Seven of Germany's Scientists Working at Point Mugu Center

Seven German scientists—experts on Nazi secret weapons in World War II—today are working at the Navy's Guided Missile Test Center, Point Mugu, under voluntary government contracts, The Times learned yesterday.

They are Dr. Herbert Alois Wagner, Dr. Reinhard Natanael Lahde, Dr. Wilfred Hermann Hell, Dr. Theodore Friedrich Sturm, Dr. Ernest O. Freiderich, Dr. Edgar R. Kutsscher and Dr. Hane Erich Holman.

While they are not permitted to work on new Navy developments in the mysterious field of "push-button" warfare, their research parallels that of American scientists at the test center in that they are completing war-time projects begun for Hitler.

Their Work for Nazis

Exact nature of their studies was not disclosed, but it was learned Dr. Wagner directed Germany's program for development of air-to-ground and ground-to-air missiles, with Dr. Lahde and Dr. Hell as associates, while Dr. Sturm was in charge of remote control and guidance *for rockets, bombs* and other missiles.

Dr. Hell is said to be an authority on remote-control mechanisms while Dr. Lahde specializes in gas turbine and bombsight equipment.

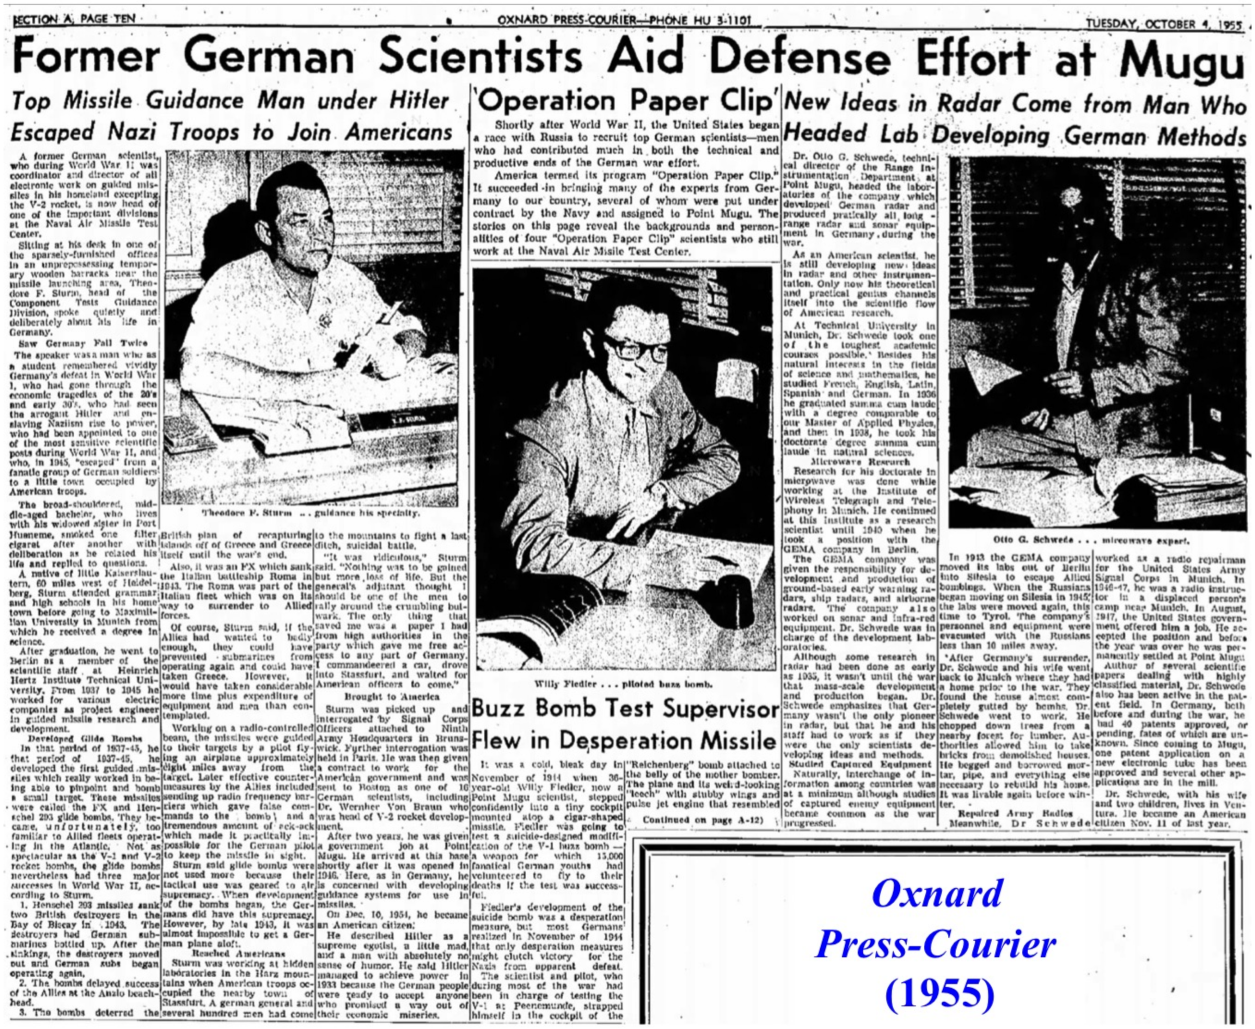
All reportedly have applied for U.S. citizenship, and three of the scientists—Dr. Wagner, Dr. Lahde and Dr. Hell—have their families with them in nearby Oxnard.

Bid for Their Families

The others have asked that their families be brought to the United States, including some relatives who were in Russian-occupied territory at the war's end—when the scientists themselves were being questioned by U.S. intelligence officers.

The Point Mugu center is regarded as one of the Navy's top projects, and the House Armed Services Committee recently approved a $34,520,000 allocation for construction work at the base.

Primary purpose of the installation is to test and evaluate the many secret remote-controlled "birds" now being developed by the Navy to keep America abreast of similar weapons-of-the-future also sought by other nations.



SECTION A, PAGE TEN — OXNARD PRESS-COURIER—PHONE HU 3-1101 — TUESDAY, OCTOBER 4, 1955

Former German Scientists Aid Defense Effort at Mugu

Top Missile Guidance Man under Hitler Escaped Nazi Troops to Join Americans

A former German scientist, who during World War II was coordinator and director of all electronic work on guided missiles in his homeland excepting the V-2 rocket, is now head of one of the important divisions at the Naval Air Missile Test Center.

Sitting at his desk in one of the sparsely-furnished offices in an unprepossessing temporary wooden barracks near the missile launching area, Theodore F. Sturm, head of the Component Tests Guidance Division, spoke quietly and deliberately about his life in Germany.

Saw Germany Fall Twice

The speaker was a man who as a student remembered vividly Germany's defeat in World War I, who had gone through the economic tragedies of the 20's and early 30's, who had seen the arrogant Hitler and enslaving Naziism rise to power, who had been appointed to one of the most sensitive scientific posts during World War II, and who, in 1945, "escaped" from a fanatic group of German soldiers to a little town occupied by American troops.

Theodore F. Sturm . . . guidance his specialty.

The broad-shouldered, middle-aged bachelor, who lives with his widowed sister in Port Hueneme, smoked one filter cigaret after another with deliberation as he related his life and replied to questions.

A native of little Kaiserslautern, 60 miles west of Heidelberg, Sturm attended grammar and high schools in his home town before going to Maximillian University in Munich from which he received a degree in science.

After graduation, he went to Berlin as a member of the scientific staff at Heinrich Hertz Institute Technical University. From 1937 to 1945 he worked for various electric companies as project engineer in guided missile research and development.

Developed Glide Bombs

In that period of 1937-45, he that period of 1937-45, he developed the first guided missiles which really worked in being able to pinpoint and bomb a small target. These missiles were called the FX and Henschel 293 glide bombs. They became, unfortunately, too familiar to Allied fleets operating in the Atlantic. Not as spectacular as the V-1 and V-2 rocket bombs, the glide bombs nevertheless had three major successes in World War II, according to Sturm.

1. Henschel 293 missiles sank two British destroyers in the Bay of Biscay in 1943. The destroyers had German submarines bottled up. After the sinkings, the destroyers moved out and German subs began operating again.
2. The bombs delayed success of the Allies at the Anzio beachhead.
3. The bombs deterred the British plan of recapturing islands off of Greece and Greece itself until the war's end.

Also, it was an FX which sank the Italian battleship Roma in 1943. The Roma was part of the Italian fleet which was on its way to surrender to Allied forces.

Of course, Sturm said, if the Allies had wanted to badly enough, they could have prevented submarines from operating again and could have taken Greece. However, it would have taken considerable more time plus expenditure of equipment and men than contemplated.

Working on a radio-controlled beam, the missiles were guided to their targets by a pilot flying an airplane approximately eight miles away from the target. Later effective countermeasures by the Allies included sending up radio frequency barriers which gave false commands to the bombs and a tremendous amount of ack-ack which made it practically impossible for the German pilot to keep the missile in sight.

Sturm said glide bombs were not used more because their tactical use was geared to air supremacy. When development of the bombs began, the Germans did have this supremacy. However, by late 1943, it was almost impossible to get a German plane aloft.

Reached Americans

Sturm was working at hidden laboratories in the Harz mountains when American troops occupied the nearby town of Stassfurt. A german general and several hundred men had come to the mountains to fight a last ditch, suicidal battle.

"It was ridiculous," Sturm said. "Nothing was to be gained but more loss of life. But the general's adjutant thought I should be one of the men to rally around the crumbling bulwark. The only thing that saved me was a paper I had from high authorities in the party which gave me free access to any part of Germany. I commandeered a car, drove into Stassfurt, and waited for American officers to come."

Brought to America

Sturm was picked up and interrogated by Signal Corps Officers attached to Ninth Army Headquarters in Brunswick. Further interrogation was held in Paris. He was then given a contract to work for the American government and was sent to Boston as one of 16 German scientists, including Dr. Wernher Von Braun who was head of V-2 rocket development.

After two years, he was given a government job at Point Mugu. He arrived at this base shortly after it was opened in 1946. Here, as in Germany, he is concerned with developing guidance systems for use in missiles.

On Dec. 10, 1954, he became an American citizen.

He described Hitler as a supreme egotist, a little mad, and a man with absolutely no sense of humor. He said Hitler managed to achieve power in 1933 because the German people were ready to accept anyone who promised a way out of their economic miseries.

'Operation Paper Clip'

Shortly after World War II, the United States began a race with Russia to recruit top German scientists—men who had contributed much in both the technical and productive ends of the German war effort.

America termed its program "Operation Paper Clip." It succeeded in bringing many of the experts from Germany to our country, several of whom were put under contract by the Navy and assigned to Point Mugu. The stories on this page reveal the backgrounds and personalities of four "Operation Paper Clip" scientists who still work at the Naval Air Misile Test Center.

Willy Fiedler . . . piloted buzz bomb.

Buzz Bomb Test Supervisor Flew in Desperation Missile

It was a cold, bleak day in November of 1944 when 36-year-old Willy Fiedler, now a Point Mugu scientist, stepped confidently into a tiny cockpit mounted atop a cigar-shaped missile. Fiedler was going to test a suicide-designed modification of the V-1 buzz bomb — a weapon for which 15,000 fanatical German youths had volunteered to fly to their deaths if the test was successful.

Fiedler's development of the suicide bomb was a desperation measure, but most Germans realized in November of 1944 that only desperation measures might clutch victory for the Nazis from apparent defeat.

The scientist and pilot, who during most of the war had been in charge of testing the V-1 at Peenemunde, strapped himself in the cockpit of the "Reichenberg" bomb attached to the belly of the mother bomber. The plane and its weird-looking "leech" with stubby wings and pulse jet engine that resembled

Continued on page A-12)

New Ideas in Radar Come from Man Who Headed Lab Developing German Methods

Dr. Otto G. Schwede, technical director of the Range Instrumentation Department at Point Mugu, headed the laboratories of the company which developed German radar and produced pratically all long-range radar and sonar equipment in Germany during the war.

As an American scientist, he is still developing new ideas in radar and other instrumentation. Only now his theoretical and practical genius channels itself into the scientific flow of American research.

At Technical University in Munich, Dr. Schwede took one of the toughest academic courses possible. Besides his natural interests in the fields of science and mathematics, he studied French, English, Latin, Spanish and German. In 1936 he graduated summa cum laude with a degree comparable to our Master of Applied Physics, and then in 1938, he took his doctorate degree summa cum laude in natural sciences.

Microwave Research

Research for his doctorate in microwave was done while working at the Institute of Wireless Telegraph and Telephony in Munich. He continued at this Institute as a research scientist until 1940 when he took a position with the GEMA company in Berlin.

The GEMA company was given the responsibility for development and production of ground-based early warning radars, ship radars, and airborne radars. The company also worked on sonar and infra-red equipment. Dr. Schwede was in charge of the development laboratories.

Although some research in radar had been done as early as 1935, it wasn't until the war that mass-scale development and production began. Dr. Schwede emphasizes that Germany wasn't the only pioneer in radar, but that he and his staff had to work as if they were the only scientists developing ideas and methods.

Studied Captured Equipment

Naturally, interchange of information among countries was at a minimum although studies of captured enemy equipment became common as the war progressed.

Otto G. Schwede . . . mircowave expert.

In 1943 the GEMA company moved its labs out of Berlin into Silesia to escape Allied bombings. When the Russians began moving on Silesia in 1945, the labs were moved again, this time to Tyrol. The company's personnel and equipment were evacuated with the Russians less than 10 miles away.

After Germany's surrender, Dr. Schwede and his wife went back to Munich where they had a home prior to the war. They found the house almost completely gutted by bombs. Dr. Schwede went to work. He chopped down trees from a nearby forest for lumber. Authorities allowed him to take bricks from demolished houses. He begged and borrowed mortar, pipe, and everything else necessary to rebuild his home. It was livable again before winter.

Repaired Army Radios

Meanwhile, Dr Schwede worked as a radio repairman for the United States Army Signal Corps in Munich. In 1946-47, he was a radio instructor in a displaced person's camp near Munich. In August, 1947, the United States government offered him a job. He accepted the position and before the year was over he was permanently settled at Point Mugu.

Author of several scientific papers dealing with highly classified material, Dr. Schwede also has been active in the patent field. In Germany, both before and during the war, he had 40 patents approved, or pending, fates of which are unknown. Since coming to Mugu, one patent application on a new electronic tube has been approved and several other applications are in the mill.

Dr. Schwede, with his wife and two children, lives in Ventura. He became an American citizen Nov. 11 of last year.

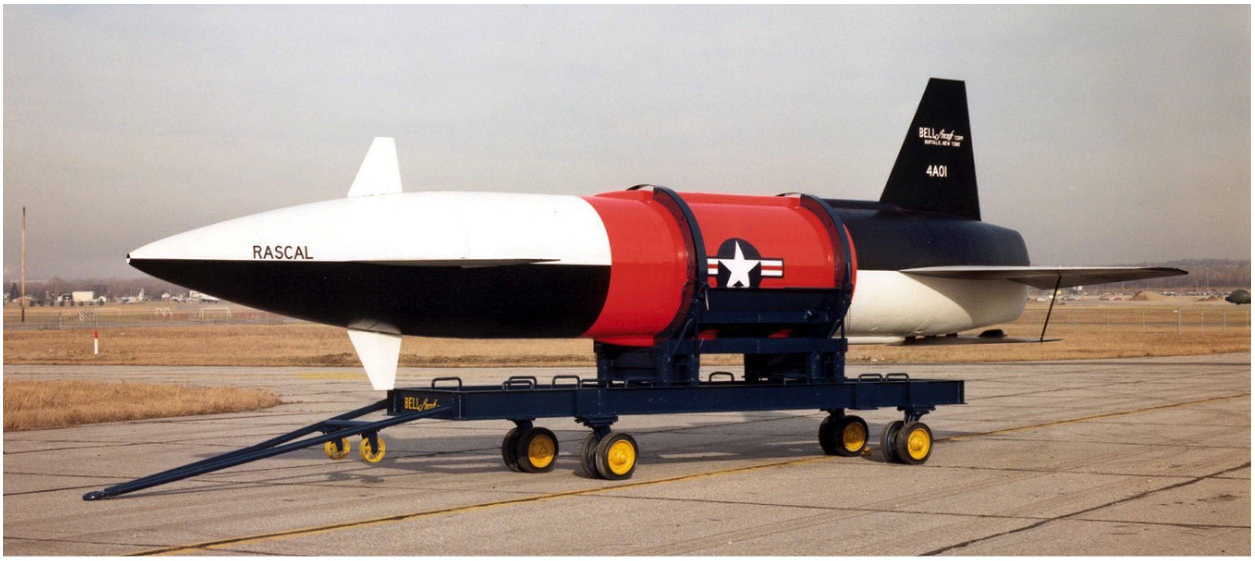
Figure 9.163: German hardware and knowledge and German-speaking scientists led to the development of the U.S. Air Force Matador cruise missile (first flight 1949), U.S. Navy Regulus cruise missile (first flight 1951), and other postwar cruise missiles.



Bell GAM-63 RASCAL air-launched cruise missile (designed by Walter Dornberger in 1946, first launched in 1953)

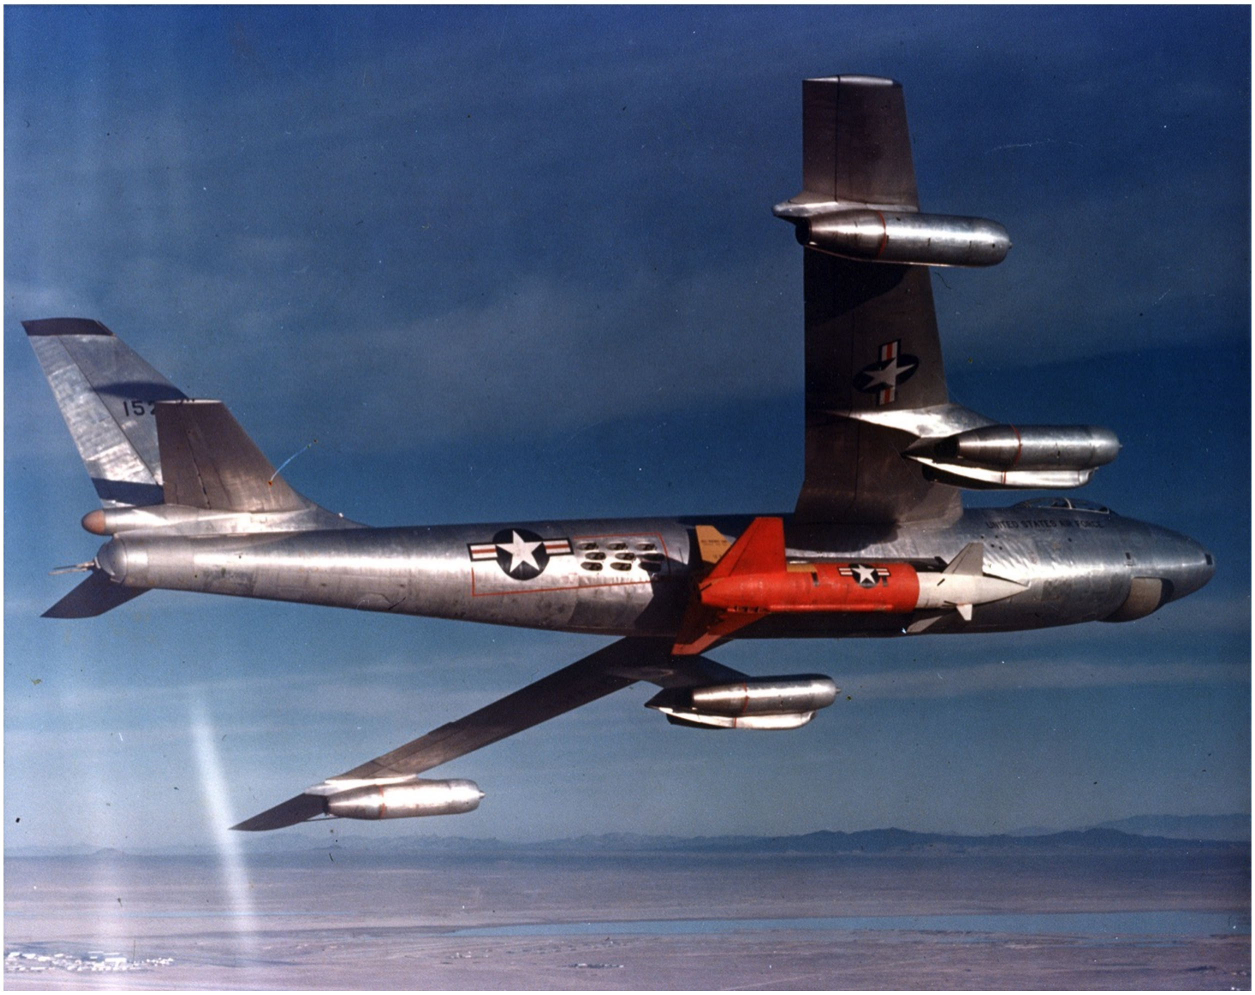


Figure 9.164: The Bell GAM-63 RASCAL air-launched cruise missile was designed by Walter Dornberger in 1946 and first launched in 1953. Essentially it was a German-derived liquid propellant rocket that was intermediate in size between the Wasserfall (p. 1844) and A-4/V-2 (p. 1860) and was deployed like the air-launched V-1 (p. 1841).

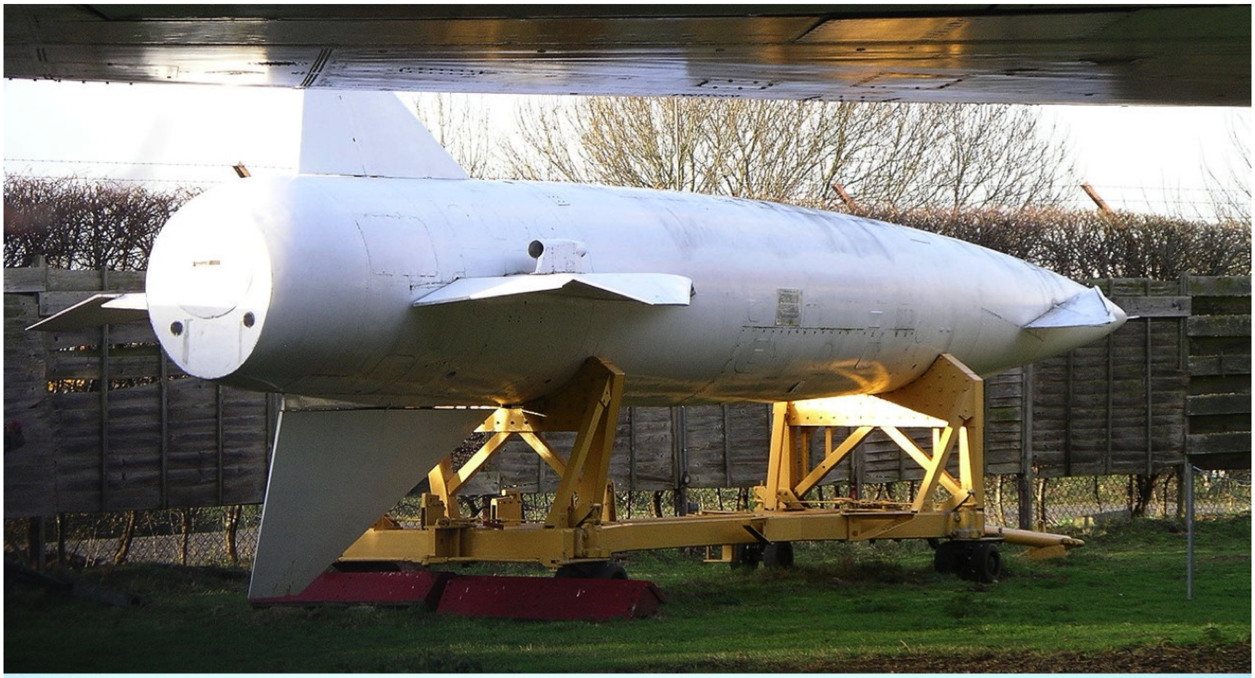

The Avro Blue Steel air-launched cruise missile carried by Vulcan and Victor bombers (deployed in 1963) was essentially the British version of Walter Dornberger's Bell GAM-63 RASCAL

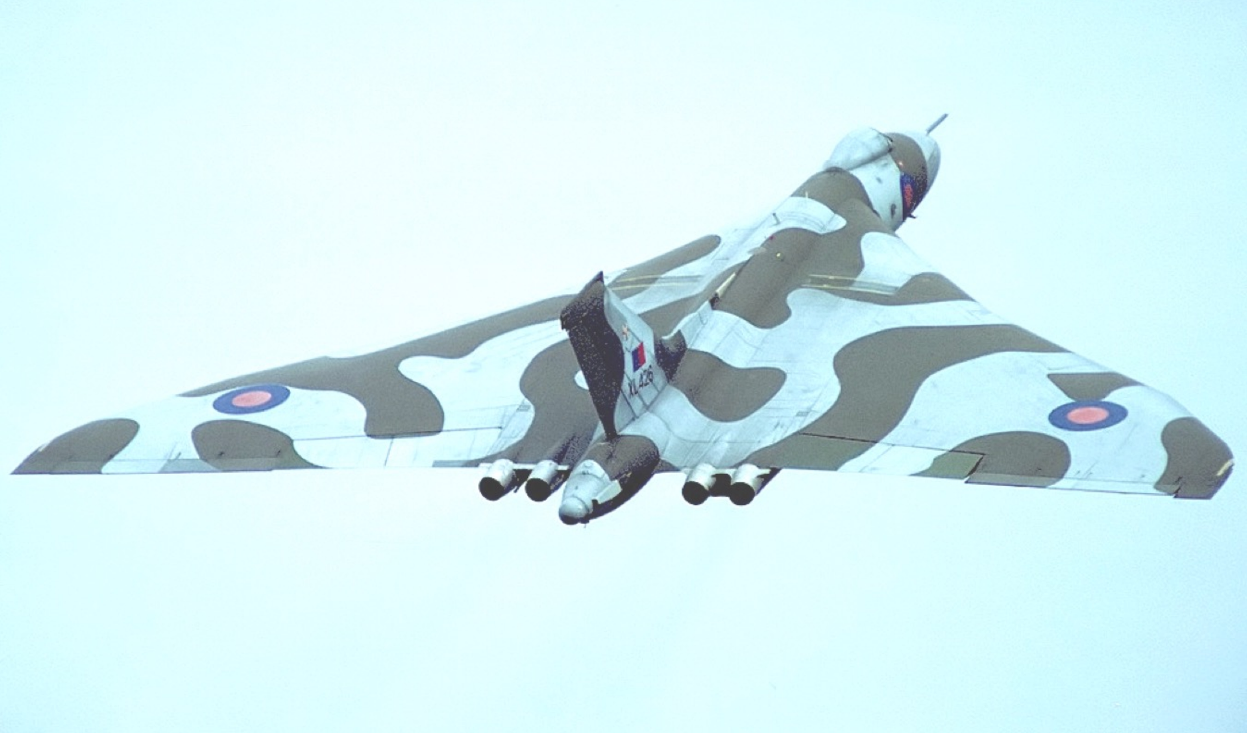

Figure 9.165: The Avro Blue Steel air-launched cruise missile carried by Vulcan and Victor bombers (deployed in 1963) was essentially the British version of Walter Dornberger's Bell GAM-63 RASCAL (p. 1854).

9.7 Large Liquid Propellant Rockets

Perhaps the best-known contributions (though dimming with time as the memories become more distant) of German-speaking scientists were the development of large rockets and spacecraft. German-speaking creators led the development of all types of rocket-related technologies in Germany during World War II and in countries around the world after the war.

Probably the most publicly visible rocket-related technology is liquid propellant rockets, which carry a liquid fuel and liquid oxidizer and burn them together to produce thrust, as shown in Fig. 9.166 [Hill and Peterson 1991; Huzel and Huang 1992; George Sutton 1992]. As illustrated in the upper part of the figure, the fuel and oxidizer are burned in a special combustion chamber, generating a gas that initially has a very high temperature (thermal energy) and high pressure (potential energy) but little velocity (kinetic energy). That gas then expands as it flows out through a nozzle, converting much of the initial thermal and potential energy into kinetic energy of a high-velocity exhaust stream. As shown in the lower part of the figure, it is necessary to pressurize the oxidizer and fuel from the storage tanks before they can be injected into the combustion chamber, since the gas pressure inside the combustion chamber is so high. Smaller, simpler liquid propellant rockets use high-pressure gas to pressurize the propellant in the tanks, but larger liquid propellant rockets usually use a turbopump to raise the pressure of the fuel and oxidizer just before they are injected into the combustion chamber. Small amounts of fuel and oxidizer are diverted to power the turbopump, or sometimes the turbopump is powered by an entirely separate supply of propellant. In order to cool the engine and to preheat the fuel, usually fuel first detours through coils wrapping the combustion chamber and nozzle.

This section covers the development of liquid propellant rockets by German-speaking creators who worked in:

9.7.1. Pre-war and wartime German rocket programs

9.7.2. Postwar U.S. and U.K. rocket programs

9.7.3. Postwar Soviet rocket programs

9.7.4. Postwar French rocket programs

German-speaking scientists also made important contributions to postwar rocket programs in many other countries around the world, but those are not covered here.

Figure 9.166: Liquid propellant rocket design. (a) Burning of fuel and oxidizer in the combustion chamber generates hot gas with velocity $v_{\text{chamber}} \approx 0$, pressure p_{chamber}, and temperature T_{chamber}, which expands in the nozzle until it has exhaust values v_{exh}, p_{exh}, and T_{exh}. (b) Pumps raise the pressure of oxidizer and fuel from the storage tanks and inject it into the combustion chamber. Along the way, fuel detours through coils wrapping the combustion chamber and nozzle, cooling the engine and preheating the fuel. Small amounts of oxidizer and fuel are diverted to burn in a gas generator, producing hot exhaust that powers a gas turbine and thereby the pumps.

9.7.1 Pre-War and Wartime German Rocket Programs

Hermann Oberth (Austro-Hungarian, 1894–1989), shown in Fig. 9.167, began experimenting with rockets in 1908 when he was only 14. By the early 1920s, he was publishing detailed and highly influential designs and analyses of rockets [Oberth 1929, 1984].

Oberth was the scientific consultant for Fritz Lang's 1929 film, *Frau im Mond* (*Woman in the Moon*, p. 1971),[13] which depicted how astronauts could use a rocket to travel to the moon, and which profoundly influenced a whole generation of young German rocket engineers such as Werner von Braun (German, 1912–1977). Among other prophetic details, the film showed the construction of the rocket in a large vehicle assembly building, the transport of the rocket to a launch pad, a countdown to the launch, horizontal couches for the astronauts during launch, the use and ejection of multiple rocket stages during the ascent, the effects of zero gravity in space, etc.

Oberth advised and assisted the younger rocket engineers during the 1930s and 1940s, and continued to promote spaceflight in Europe and the United States after the war.

In the early development of liquid propellant rockets, the closest competitor outside the German-speaking world was probably Robert Goddard (American, 1882–1945) [Lehman 1988]. Despite Goddard's promising ideas and experiments, he never was able to obtain much U.S. political and financial support for his research, in stark contrast to the enormous support that the German-speaking engineers received. By the time of Goddard's death in 1945, German rockets were many years ahead of anything that Goddard had been able to accomplish with his limited support.

From 1933 to 1945, Wernher von Braun (German, 1912–1977) led a team that developed a series of increasingly sophisticated liquid propellant rockets, initially at Kummersdorf, then at Peenemünde. Von Braun was closely backed by the strong political support of Walter Dornberger (German, 1895–1980, Fig. 9.223), a general in the German army. By far their most famous creation was the A-4 or V-2 rocket, which was first launched in 1942 and was capable of reaching altitudes over 200 km (beyond the earth's atmosphere and well into outer space). See Fig. 9.168.[14]

Although German-designed rockets certainly went all the way to the moon after the war, there is considerable evidence that even wartime German rockets may have advanced significantly beyond the single-stage A-4 or V-2 rocket. As presented in Appendix E, there is documentation reporting wartime research, development, and even testing of larger rockets with longer ranges and larger payloads, two-stage intercontinental ballistic missiles, submarine-launched missiles, advanced solid propellant rockets, prototype manned space planes (A-9 and Silbervogel), and advanced rocket engines (hydrogen/oxygen, ion, and fission thermal). Appendix E gives an overview of currently known evidence for these wartime advanced rocket developments, but this is clearly another area where much more archival research is needed to clarify exactly what work was done and by whom, and precisely how it guided postwar missile, rocket, and space programs in the United States, the Soviet Union, and other countries.

9.7.2 Postwar U.S. and U.K. Rocket Programs

At the end of the war, von Braun and much of his team moved to the United States, where they spent a quarter-century developing a series of even larger rockets, both for ballistic missile programs (Fig. 9.169) and also for the space program. Their work culminated in the Saturn V rocket that carried the Apollo missions to the moon in 1968–1972 (Figs. 9.170–9.171). Dornberger also moved to the United States and worked separately on a series of rocket planes, culminating in the U.S. Space Shuttle (pp. 1854 and 1927–1932).[15]

U.S. Army Lt. Colonel William E. Winterstein worked very closely with von Braun immediately after his arrival in the United States, and he later emphasized how long von Braun had planned and lobbied for manned missions to the moon [Winterstein 2005, pp. 34–35]:

> Among the many discussions I had with Wernher [von Braun] during those days was the theme of space exploration. The first step, naturally, was a voyage to the Moon. This was his lifelong ambition. At that time, the outlook for any rocket research for such a project was unfavorable. [...]
>
> In the summer of 1946, I asked Wernher "If we could give you all of the money you wanted, how much, and how long, would it take you to put Man on the Moon?" Several weeks later, he said: "Give us three billion dollars, and ten years, and we will go to the moon and back." At the time, I thought it was merely very interesting information, never dreaming of their importance.
>
> It was fifteen years later that similar words, concerning the time frame at least, were uttered by President Kennedy to a joint session of Congress on May 25th 1961. "Before this decade is out," described the time frame. Prior to President Kennedy's address to Congress, Dr. von Braun had convinced the President that the trip to the Moon was technologically possible. This further convinced me that Wernher must have done a lot of planning for a Moon mission, years before he gave me the same information concerning the time element in 1946.

Of course, von Braun and his team ultimately did exactly what they had long envisioned, once the United States finally committed the necessary amount of funding after many years of bureaucratic indecision and delays. Yet if von Braun's team had had the full financial and political support of the United States from 1945 onward, how soon might the United States have sent the first astronaut into space, or sent the first astronauts to the Moon? How much further into space might the United States have progressed after that? (And what did von Braun's apparently very knowledgeable 1946 statement to Winterstein suggest about how far the development of rockets more advanced than the A-4 had progressed in wartime Germany? See Sections E.2, E.5, and E.7.)

---

[15] Likewise, the history of postwar liquid propellant rockets has been so well documented that it will not be covered in any detail here. For more information, see: Bilstein 1980; von Braun et al. 1985; Franklin 1987; Freeman 1993; Huzel 1962; Huzel and Huang 1992; Koelle 1961; Kurowski 2001; Ley 1968; Mader 1963; Jürgen Michels 1997; Neufeld 2007; Powell-Willhite 2007; Stuhlinger and Ordway 1994a, 1994b; NYT 1945-05-23 p. 4, 1946-04-12 p. 11, 1946-04-22 p. 6, 1946-05-07 p. 3, 1946-06-29 p. 11, 1947-03-02 p. 17, 1947-06-22 p. E-7, 1948-04-03 p. 27.

When Wernher von Braun died in 1977, President Jimmy Carter issued a public statement [Carter 1977, p. 1125]:

> To millions of Americans, Wernher von Braun's name was inextricably linked to our exploration of space and to the creative application of technology. He was not only a skillful engineer but also a man of bold vision; his inspirational leadership helped mobilize and maintain the effort we needed to reach the Moon and beyond.
>
> Not just the people of our Nation but all the people of the world have profited by his work. We will continue to profit from his example.

Of course, von Braun was only one person, but President Carter's statement demonstrates how critical the German-speaking scientists had been for the space and ballistic missile programs in the United States. John Becklake, a historian of science at London's Science Museum, described the contributions of the German-speaking scientists in more detail [Becklake 1994]:

> Twenty-five years ago, in July 1969, the first men landed on the Moon. These pioneering spacefarers, Neil Armstrong and Buzz Aldrin, were launched on this mission by America's massive Saturn V rocket. Twenty-five years before this, on 8 September 1944, the first operational V2 missile was fired at Paris from a mobile launch site in the Ardennes region of France. Both of these rockets were developed by the same team of German engineers, led by Wernher von Braun. [...]
>
> The accomplishments of this US-based team, now expanded to include local engineers, are legendary—they developed the US's first long range missile (Redstone), provided the launch vehicle that orbited America's first satellite and later, under the auspices of the civil space agency, NASA, developed the Saturn family of rockets. This included the Saturn V rocket that sent the Apollo astronauts to the Moon. So influential were von Braun and his team in almost every major rocket activity in Germany and the US between 1930 and 1970, that this volume [a biography of von Braun] effectively represents a history of rocketry in the Western world.

Wernher von Braun	German	1912–1977	
Oswald Lange	German	1912–2000	
Bruce Medaris	American	1902–1990	U.S. Army General
Helmut Hölzer	German	1912–1996	
Hans Maus	German	1905–1999	
Ernst Geissler	German	1915–1989	
Hans Hueter	German	1906–1970	
George Constan	American	1909–1986	Manager, Michoud Assembly Facility

The lower photograph in Fig. 9.172 shows the attendees of a 1961 meeting at NASA. From left to right, they were:

Name	Born	Lived	Role
Werner Kuers	German	1907–1983	Director, Manufacturing Engineering Division
Walter Häussermann	German	1914–2010	Director of the Astrionics Division
William Mrazek	German	1911–1992	Propulsion and Vehicle Engineering Division
Wernher von Braun	German	1912–1977	Director of Marshall Space Flight Center
Dieter Grau	German	1913–2014	Director of the Quality Assurance Division
Oswald Lange	German	1912–2000	Director of the Saturn Systems Office
Erich W. Neubert	German	1910–1999	Assoc. Deputy Director, Research/Development

For a more extensive list of German-speaking scientists/engineers who worked in postwar U.S. and U.K. rocket and missile programs, see Table 9.2. (There was a relatively free exchange of German-speaking scientists and information between the U.S. and U.K. programs, so they are treated together here.) Even this list represents only a fraction of the many hundreds of German-speaking scientists and engineers who worked in all parts of NASA, military research centers, and aerospace and electronics companies to make the U.S. and U.K. missile, rocket, and space programs possible.

For examples of U.K. rockets designed by German-speaking scientists, including Black Knight, Blue Streak, Europa, and Black Arrow, see pp. 1870–1872 and p. 5576.

The German-speaking creators developed these revolutionary inventions from scratch to fully mature technologies during their careers. Even now, many decades later, these same German creations are still repackaged by others as “new” inventions (Fig. 9.177).

SpaceX Merlin 1D RP-1/ liquid oxygen engine with gas generator (2012)
Copied from von Braun team's H-1 engine, but it produces less thrust than the H-1

Figure 9.177: Based on their earlier A-4 and Redstone engines, Wernher von Braun's team designed RP-1/liquid oxygen engines with gas generators: the Jupiter S-3 (first operational in 1955) and the Saturn H-1 (first operational in 1963). The much-hyped SpaceX Merlin 1D engine (first operational in 2012) was directly copied from the H-1 engine yet produces less thrust than the H-1.

9.7.3 Postwar Soviet Rocket Programs

German-speaking engineers, designs, and materials also greatly contributed to the development of missiles, rockets, and spacecraft in the Soviet Union.[16]

Huge numbers of German-speaking scientists and engineers were employed (willingly or otherwise) in postwar Soviet rocket and missile programs (p. 2064). Table 9.3 lists some examples. Helmut Gröttrup (German, 1916–1981) was the most prominent scientific leader and coordinator among the German-speaking engineers. Figure 9.178 shows an October 1947 photo at the Kapustin Yar rocket testing site, where Gröttrup posed with Karl Viktor Stahl, Johannes Hoch, Fritz Viebach, and Hans-Albert Vilter.

Figure 9.179 presents the first three major types of Soviet ballistic missiles (see also p. 5797):

- The SS-1 or R-1 Scunner was basically just an A-4/V-2 rocket (14 meters long) that was manufactured by Germans under Soviet control and used 1950–1953.
- The SS-2 or R-2 Sibling was a longer, upgraded A-4 (18 meters long) that was in service 1953–1956. Not only was it produced by German engineers, but it appears to have been copied from 18-meter extended A-4 rockets that were secretly developed and tested in Germany during the war (p. 5794).
- The SS-3 or R-5M Shyster, also shown in Fig. 9.180, was an even longer upgraded A-4 (21 meters long) that was in service 1956–1967. It was again created by German engineers, also apparently based on wartime work (p. 5794). In fact, with its 1200 km range, capable of delivering a nuclear warhead to anywhere in the United Kingdom from dedicated launch sites near Peenemünde, the SS-3 appears to have been the very embodiment of wartime German plans (p. 5575).

Later Soviet rockets, including those still used by Russia today, were also the product of German-speaking engineers working in the Soviet Union:

- The clustered design of the R-7 or SS-6 Sapwood and all later Russian rockets was directly derived from Helmut Gröttrup's G-5 design, as illustrated in Fig. 9.181 [http://www.astronautix.com/g/g-5.html].
- The RD-107/RD-108 engines of the R-7 and all later Russian rockets were directly derived from engine designs by Werner Baum (German, 1918–20??), as shown in Fig. 9.182 [Przybilski 2002a].
- Figure 9.183 illustrates how Helmut Gröttrup's rocket designs and Werner Baum's engines were used for the R-7, Sputnik, Vostok, Voshkod, and Soyuz launchers.
- Soyuz rockets are still used by Russia for launches to the International Space Station (Fig. 9.184).

9.7.4 Postwar French Rocket Programs

Similarly, German-speaking scientists and engineers made major contributions to postwar programs in France. Writing for *L'Express*, investigative journalists Vincent Nouzille and Olivier Huwart researched unclassified French government records and described the recruitment and ultimate technological impact of over 1000 German and Austrian scientists and engineers in France after the war, especially with regard to missiles and other aerospace technologies [Nouzille and Huwart 1999].

For some examples of German-speaking contributions to postwar French rockets, including Véronique, Diamant, and Ariane, see Table 9.4 and Figs. 9.185–9.189 [Jürgen Michels 1997]. Later the German-designed Viking engine and other Ariane technologies were licensed to India, which built copies for its space program (p. 1889).

For more information on German-designed rockets in France, see pp. 5576–5584.

ABSTRACT: A turbopump is provided for a liquid-fuel rocket engine using two power propellants, namely a noncryogenic oxidizer and a noncryogenic fuel. The turbopump feeds the rocket engine at high pressure. The pump-driving turbine of the turbopump is fed by gases from a generator produced by the combustion of the two propellants and cooled by the injection of water. A regulator is connected between the generator and the propellant pumps of the turbopump to control the speed of the turbine in accordance with engine combustion pressure to maintain a substantially constant pressure. The propellants are fed to the engine injection via a balancing device which regulates the propellant delivery pressures so that they are equalized.

9.8 Submarine-Launched and Solid Propellant Rockets

Section 9.8.1 concerns submarine-launched missiles that were developed or were under development during the war, as well as the postwar influence of such projects and German-speaking scientific experts.

Section 9.8.2 covers the wartime and postwar development of solid propellant rockets.

Not all submarine-launched missiles used solid propellant, and not all solid propellant rockets were designed to be launched from submarines, but the two histories are so deeply intertwined (because solid propellant is especially desirable for submarine-launched rockets) that they are presented together here.

A number of supporting documents are presented in Appendix E.

9.8.1 Submarine-Launched Missiles

Several submarine-launched missile prototypes and designs were developed in wartime Germany:

- In May 1942, there was a series of successful tests to launch small Nebelwerfer rockets from a submerged submarine (U-511). Those tests were documented in a June 1942 report [Bundesarchiv Militärarchiv Freiburg RH 8/369]. See pp. 1892 and 5631–5639.

- Based on those successful initial tests, during 1942–1945, the German Navy sponsored the development of a whole series of increasingly sophisticated short-range rockets that could be launched from a submerged submarine. Those rockets were successfully demonstrated at Toplitz See, Austria. The rockets and testing equipment were all destroyed at the end of the war as American forces approached. After the war, though, U.S. Navy investigators interrogated several of the engineers who were involved in the project and wrote a report about their work [NavTecMisEu 500-45]. See pp. 1893 and 5640–5645.

- Also based on the 1942 tests and the proposal by Lafferenz, engineers from Peenemünde began working on the “Prüfstand XII” project to transport and launch A-4 (V-2) rockets from specially designed underwater cargo containers that could be towed by submarines. For examples from a large collection of 1944 design drawings [Bundesarchiv Militärarchiv Freiburg RH 8/4067K], see pp. 1894 and 5646–5654. Although in Dornberger’s postwar public statements he said that nothing ever came of the project, it is unclear how far the project may have actually progressed. There were reports that at least one Prüfstand XII unit may have been constructed and tested before the end of the war.

- There were also wartime programs to launch modified V-1 cruise missiles from German submarines (pp. 5618–5627).

These and other wartime German projects were continued in other countries after the war, with the aid of German-speaking scientists and captured German hardware and plans:

- As part of Operation Sandy, the U.S. Navy launched an A-4 (V-2) rocket from the deck of the USS Midway on 6 September 1947, demonstrating that an A-4 rocket could indeed be transported and launched at sea (p. 1895).

- Beginning in February 1947, Loon missiles, U.S. copies of German V-1 cruise missiles [Quigg 2014], were launched from the USS *Cusk* submarine, based on wartime German developments and implemented by German-speaking scientists at Point Mugu Naval Air Missile Test Center. That program was even marketed as a great American achievement in magazines (e.g., p. 1896) and in a fictionalized Hollywood film (*The Flying Missile*, 1950, Columbia Pictures). See also p. 5627.

- German-speaking scientists and technologies were used to develop a series of more advanced U.S. cruise missiles beginning in the late 1940s (pp. 1850–1854).

- Wernher von Braun's team was directly involved in developing Jupiter, a liquid propellant ballistic missile designed to be launched from submarines (but ultimately only deployed on land; see p. 1897).

- German-speaking scientists were deeply involved in the development of U.S. solid propellant submarine-launched ballistic missiles (SLBMs) in ways that have never been fully disclosed to the public (pp. 1902–1904 and 5700–5736).

- In 1962, Robert Truax at Aerojet proposed to greatly scale up the "Prüfstand XII" approach to create the Sea Dragon, a sea-launched rocket that would have been larger than even a Saturn V (p. 5655).

- The Soviet Union also investigated versions of the "Prüfstand XII" approach as part of its postwar Golem program to develop SLBMs.[17]

- The first Soviet SLBM, the R-11FM Zemlya (SS-1B SCUD-A), was directly based on the German Wasserfall (first launched in 1944). Like the Wasserfall, it used storable liquid propellants. The R-11FM was first launched from a submarine on 16 September 1955. See pp. 1898–1899.

- Later generations of Soviet SLBMs, such as the R-13 (SS-N-4, first launched in 1959) and R-21 (SS-N-5, first launched in 1962) were scaled up from the R-11FM and again were directly based on German-developed technologies and propellants (p. 1900).

- German-speaking scientists and technologies likely also had a great impact on the postwar submarine-launched missile programs of other countries (e.g., p. 5660).

9.8.2 Solid Propellant Rockets

German-speaking creators made huge contributions to large solid propellant rockets.[18] Although solid propellant rockets have lower exhaust velocities than liquid propellant rockets, they can generally be stored for years without degradation. Therefore, they are primarily used for military rockets and "off-the-shelf" boosters that can be strapped to the side of the first stage of a spacecraft launch vehicle. For submarine-launched rockets, where it is necessary to be able to store the rockets stably and safely for years and yet fire them on very short notice, solid propellants are highly preferable to liquid propellants.

Most large solid propellant rockets typically contain a mixture of:[19]

- $\sim$ 70% (by mass) powdered crystalline oxidizer, usually ammonium perchlorate but sometimes potassium perchlorate, ammonium nitrate, potassium nitrate, cyclotrimethylene trinitramine (RDX), or cyclotetramethylene tetranitramine (HMX).
- $\sim$ 15% powdered metal fuel, usually aluminum but sometimes magnesium, zinc, or zirconium.
- $\sim$ 15% binder, a polymer that both holds the powdered oxidizer and metal fuel in place (while withstanding high thermal and mechanical stresses) and also serves as additional fuel that can react with the oxidizer. Binders are usually derivatives of polybutadiene (buna synthetic rubber), polyurethane, polyalkylene, or polyvinyl chloride.
- $\sim$ 1% or less of other ingredients that may act as curing agents (to cross-link the polymer binder), plasticizers (to make the propellant more flexible and therefore less likely to crack), stabilizers (to slow chemical degradation of the propellant during years of storage), etc.

Instead of the above propellant mixture, missiles that must minimize their smoke (e.g., so it is harder to see them coming) tend to use double-base propellants such as a mixture of nitroglycerin and nitrocellulose.

As shown in Fig. 9.200, solid propellant burns along its exposed surfaces, releasing hot exhaust gases through the nozzle until the propellant is used up or the thrust termination port is opened. An igniter (not shown) initiates the combustion. For all practical purposes, solid propellant rockets cannot be shut down and restarted later, unlike liquid propellant rockets.

The exposed surfaces in a solid propellant rocket may be molded into different patterns or propellant grain designs (Fig. 9.200). Progressive solid propellant grain designs have cross-sectional patterns of exposed surfaces (e.g., tubular or perforated) such that the exposed surface area and hence the thrust increase as the rocket burns. Neutral grain designs (e.g., rod and tube or star) have approximately the same exposed surface area and thrust during most of their burn time. Regressive grain designs (e.g., slotted or double anchor) have a decreasing exposed surface area and thrust as the rocket burns. For more complicated thrust profiles, solid propellant rockets may even change the grain design along the length of the rocket, or use different solid propellants that are exposed at different times during the engine burn.

---

[18] Benecke and Quick 1957; Christopher 2013; Hahn 1998; Nagel 2011, 2012a; BIOS 27; BIOS 31; BIOS 100; BIOS 571; BIOS 1261; NavTecMisEu 327-45.

[19] [Brooks 1972; Scortia and Cutforth 1971; Hill and Peterson 1991; George Sutton 1992.

Like liquid propellant rockets, solid rockets may be steered by any of several mechanisms during their burn, including tilting the nozzle (if it is connected to the propellant case by a flexible yet heat-resistant seal or joint), injecting fluid into one side of the exhaust to divert the rest of the hot exhaust gas, or moving heat-resistant rudders or vanes that protrude into the exhaust stream.

During World War II, a number of nearly forgotten German-speaking chemists and engineers, such as those shown in Figs. 9.201–9.205, successfully developed and demonstrated advanced solid propellant rockets, including for example:

- The Rochen ammonium perchlorate/polybutadiene short-range missile, first fired in 1944 (Fig. 9.206).
- The Rheintochter two-stage surface-to-air missile, first launched in 1943 (Fig. 9.207).
- The Rheinbote four-stage long-range rocket, first launched in 1943 (Fig. 9.208).
- The V-101, an ammonium perchlorate/polybutadiene propelled, 140-ton, 30-meter-tall, long-range ballistic missile that was under development when the war ended (Fig. 9.209).

Key German innovations of that solid propellant rocket technology included:

1. Ammonium perchlorate oxidizer [BIOS 31; BIOS 571].
2. Polybutadiene “buna” synthetic rubber in the propellant to act as both fuel and binder [BIOS 31; BIOS 571].
3. Plasticizers to enable the propellant to be molded into any desired shape, to adhere tightly to metal walls, and not to be prone to crumbling or brittleness [BIOS 31; BIOS 571].
4. Powdered aluminum as a fuel additive to improve performance [BIOS 27; BIOS 31; BIOS 100; BIOS 477; BIOS 1261; FIAT 1035; HEC 2434; HEC 2485; HEC 2487; NavTecMisEu 327-45].
5. Various grain designs for the combustion surface inside the propellant to give the desired variation of thrust with time [Benecke and Quick 1957, pp. 253–255; Klein 1977; BIOS 31; BIOS 1110; NavTecMisEu 327-45].

As illustrated in Figs. 9.210–9.212, this wartime German technology became the basis for large postwar solid propellant rockets, including satellite launch vehicles such as the U.S. Scout; strap-on solid rocket boosters such as those used with the U.S. Space Shuttle, Titan, and Delta rockets; submarine-launched ballistic missiles such as the U.S. Polaris, Poseidon, and Trident; and solid propellant land-based ballistic missiles such as the U.S. Minuteman and MX.

Although aerospace historian J.D. Hunley focused mainly on the work of American engineers, he could not avoid discussing the important contributions of Karl Klager (Austrian, 1908–2002) to the development of large solid-propellant rockets in the United States after the war [Hunley 1999]:

> Integral to the stories of the propellants used on large rockets and missiles, smaller tactical missiles, and a host of smaller rockets for a variety of rockets and spacecraft were the various binders, fuels, and oxidizers that went into the propellants. For example, the motors for the Polaris A1 missile designed by Aerojet featured a cast, case-bonded polyether-polyester-polyurethane composition with 15 percent aluminum and ammonium perchlorate. Karl Klager at Aerojet has been credited with being largely responsible for developing both the grain and the propellant for these motors, but the story of their development is evidently quite complex. Klager received the U. S. Navy Distinguished Public Services Award in 1958 for his work on the Polaris missile, but the development of some of the propellant ingredients predates when Klager joined Aerojet in 1950. [...]
>
> Karl Klager, who is credited with the development of HTPB [hydroxyl-terminated polybutadiene], was asked how he came to develop this low-cost, low-viscosity propellant that has become an industry standard. He said only that he started development in 1961 but waited until 1969 to propose the propellant to NASA for the Astrobee D and Astrobee F sounding rockets on which it flew successfully. Perhaps, however, Klager's response regarding how he came to discover unsymmetrical dimethylhydrazine (UDMH) (which is a liquid propellant used on the Bomarc missile, Titan 2 missile, Titan 3 and Titan 4 rockets, and other missiles and rockets) applies equally to HTPB. Klager said that he simply brought his knowledge of the science of chemistry to bear on the need for a propellant. He had earned a Ph.D. in chemistry from the University of Vienna in 1934 and had worked for several chemical firms in Europe from 1931 to 1948 before moving to the United States and starting work for Aerojet in 1950.

The journalist David Beers, who grew up surrounded by the research of his father and his father's coworkers at Lockheed, singled out the importance of Wolfgang Noeggerath for the Polaris solid-propellant missile [Beers 1996, pp. 38–39]:

> "The most beautiful missiles ever fired," a U.S. Navy Rear Admiral pronounced the nuclear-tipped A1X Polaris, having witnessed its successful submarine test on a summer day in 1960. The fully evolved, deployed Polaris, designed under the guidance of Wernher von Braun's friend and fellow former Nazi, Wolfgang Noeggerath, was capable of traveling 2,400 nautical miles in a few minutes and delivering, from its elusively mobile launchpad, three separate warheads to a single target deep within the Soviet Union—facts no doubt beautiful to a nuclear warfare strategist.

The *Baltimore Sun* reported the death of Werner Hohenner (1907–2000) another German scientist who played an important role in the development of the Polaris missile [*Baltimore Sun* 2000-11-29]:

> From 1947 until 1954, Mr. Hohenner was at the Point Mugu Naval Air Weapon Station in California, working in the Naval Ballistic Program that led to the development of the Polaris missile, the first U.S. submarine-launched ballistic missile.
>
> During the rocket's development, Mr. Hohenner prevailed over Mr. von Braun, who insisted that the rocket be fueled by liquid rather than solid fuel.

> "He brought a great knowledge ... in fuel handling, and convinced the Navy that if they followed von Braun's plan to use liquid fuel, which is dangerous, they could plan on losing a sub a year in accidents," said Robert L. Frohmuth, a retired Navy electrical engineer. "It was a breakthrough, and he was the one who got solid fuel missiles started, which are still being used today."
>
> "His greatest achievement was the development of the Polaris," said Mr. Schmitz.
>
> From 1957 until retiring in 1973, Mr. Hohenner was chief scientist at the air arm division at the Westinghouse plant in Linthicum, where he continued his work on weapon systems and ballistic missiles.

Grayson Merrill, a retired Navy Captain, also emphasized the central role of German-speaking scientists in the missile programs [Merrill 2003]:

> Shortly after this I was detailed to witness some V-2 firings at Cuxhaven staged by the British and executed by Germans from Peenemunde. It reinforced, in my mind, the correctness of choosing Point Mugu. After the firings a small group of American observers gathered in a Bremen rathskeller to quaff beer and discuss what we had seen. A rumpled fake Army Colonel named Theodore von Kármán summed up our feelings, "You young fellows must now go home and arrange to put these Germans to work. In the meantime build a test range for the missiles to come."
>
> Almost 20 years later it can be said that Point Mugu has borne out the committee's judgments. [...]
>
> Many of the LOON technical successes are traceable to the "German Scientists" who migrated to Point Mugu. These included Willy Fiedler, Robert Lusser and Otto Schwede. But Dr. Herbert A. Wagner, now deceased, deserves special mention. [...]
>
> I left in 1949 but nevertheless watched with pride as the range expanded in support of such missiles as LARK, SPARROW, REGULUS, RIGEL, POLARIS and TOMAHAWK.

Rolf Engel, Uwe Bödewadt, and Hermann Teichmann (all of whom developed and demonstrated ammonium perchlorate/polybutadiene solid rocket propellants during the war) all went to work for France after the war (p. 1883). Information on their postwar contributions is not publicly available, but presumably they were instrumental in developing modern solid-propellant missiles and rockets in France, and they may have made important contributions in other areas as well.

For much more detailed information on the contributions of German-speaking scientists and engineers to the development of large solid propellant rockets, see Section E.4.

II. Per-pulver

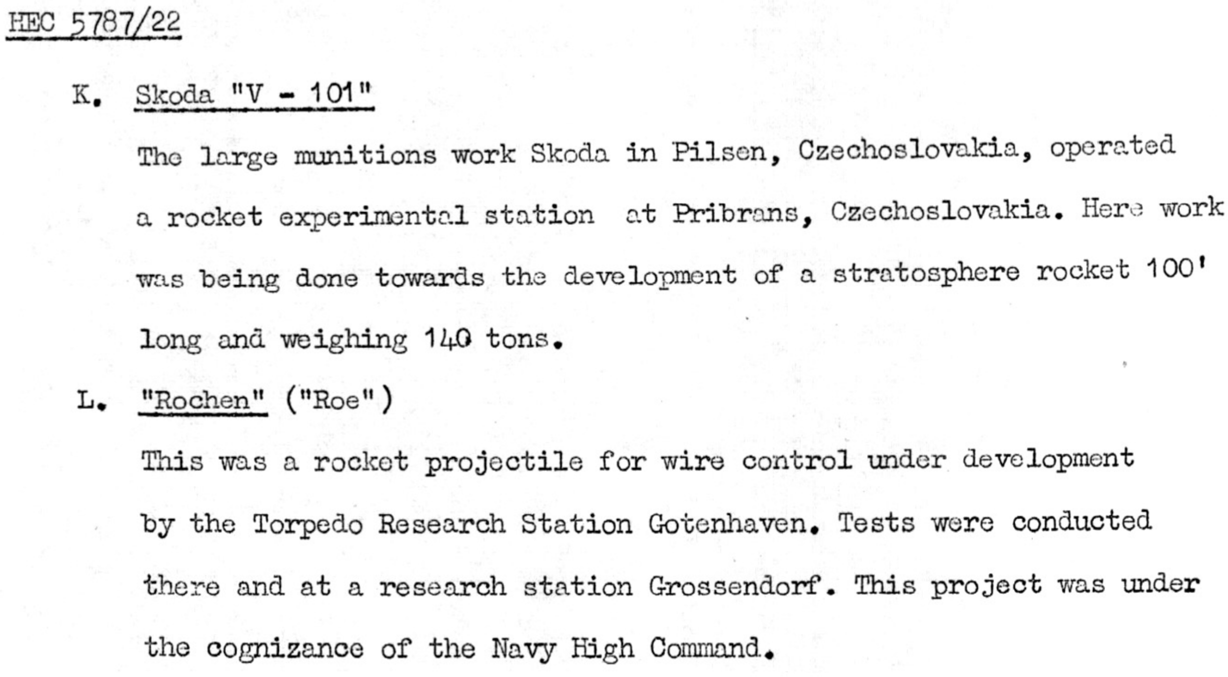
Mr. Larsson worked with the applications of this propellant to various rocket weapons, at the Skoda Works Rocket Research Station at Pibrans, Czechoslovakia, for about 6 months. Here he met the inventor of Per-pulver, Dr. Teichmann, and his two collaborators, Dr. Knust and Dr. Nord.

Per-pulver is also called Nider-druck-pulver, Super-pulver and Dauerbrand.

Composition:

Ammonium perchlorate	25 - 40%
Buna S3	25%
Vinapas	50 - 35%
Stabiliser	3 - 5%

Later interrogations of Dr. Teichmann, however, show that these figures are not exact. The composition contains about 80% of ammonium perchlotate.



HEC 5787/22

K. Skoda "V - 101"

The large munitions work Skoda in Pilsen, Czechoslovakia, operated a rocket experimental station at Pribrans, Czechoslovakia. Here work was being done towards the development of a stratosphere rocket 100' long and weighing 140 tons.

L. "Rochen" ("Roe")

This was a rocket projectile for wire control under development by the Torpedo Research Station Gotenhaven. Tests were conducted there and at a research station Grossendorf. This project was under the cognizance of the Navy High Command.

Figure 9.209: Hermann Teichmann and his collaborators invented and optimized ammonium perchlorate/polybutadiene solid rocket propellants, successfully demonstrated them in the Rochen short-range missile, and were using those propellants to develop a 140-ton, 30-meter-tall, long-range ballistic missile, the Skoda V-101, when the war ended [top: BIOS 571; bottom: HEC 5787].

9.9 Rocket Planes and Space Planes

German-speaking creators also led the way in the development of rocket planes (Section 9.9.1) and space planes (Section 9.9.2), from the first rocket plane in 1928 to the U.S. Space Shuttle.[20]

9.9.1 Rocket Planes

German-speaking scientists and engineers designed and tested numerous rocket planes from the 1920s to 1945:[21]

- Alexander Lippisch (German, 1894–1976) designed the first rocket plane, the Lippisch Ente, which was powered by two solid propellant rockets and test flown in 1928. See Fig. 9.213.
- In 1929, Fritz von Opel (German, 1899–1971) funded and piloted the second rocket plane. The Opel RAK.1 was designed and built by Julius Hatry (German, 1906–2000), with solid propellant rockets by Friedrich Sander (German, 1885–1938). See Fig. 9.213.
- In the late 1930s, engineers under Ernst Heinkel began developing and testing rocket planes using liquid propellant rocket engines, provided first by Wernher von Braun and then by Hellmuth Walter (German, 1900–1980). The culmination of that work was the Heinkel He 176, which was successfully test flown in 1939, powered by a Walter rocket engine. See Fig. 9.214.
- Shortly after that, Hellmuth Walter produced the liquid rocket engine, and Alexander Lippisch and Friedrich Otto Ringleb (German, 1900–1966) created the aircraft, for the Messerschmitt Me 163 Komet (Comet) rocket plane, the best-known German rocket plane. The Me 163 was first demonstrated in 1941, and several hundred were produced by the end of the war; see Figs. 9.215–9.216.
- In 1944, Erich Bachem (German, 1906–1960) designed the Bachem Ba 349 Natter rocket plane for vertical take-off. Several dozen were built, but they were still undergoing testing at the end of the war. See Fig. 9.217.
- Felix Kracht (German, 1912–2002) created the DFS (Deutsche Forschungsanstalt für Segelflug) 228, which was designed to be launched from a Dornier Do 217 bomber, then use a Walter rocket to climb to an altitude of up to 25 km. Two prototypes were built in 1944 but were still being tested at the end of the war. Nonetheless, the DFS 228 designs that were captured by the Allies appear to have had an enormous influence on the design of the postwar U.S. U-2 high-altitude spy plane. See Fig. 9.218.

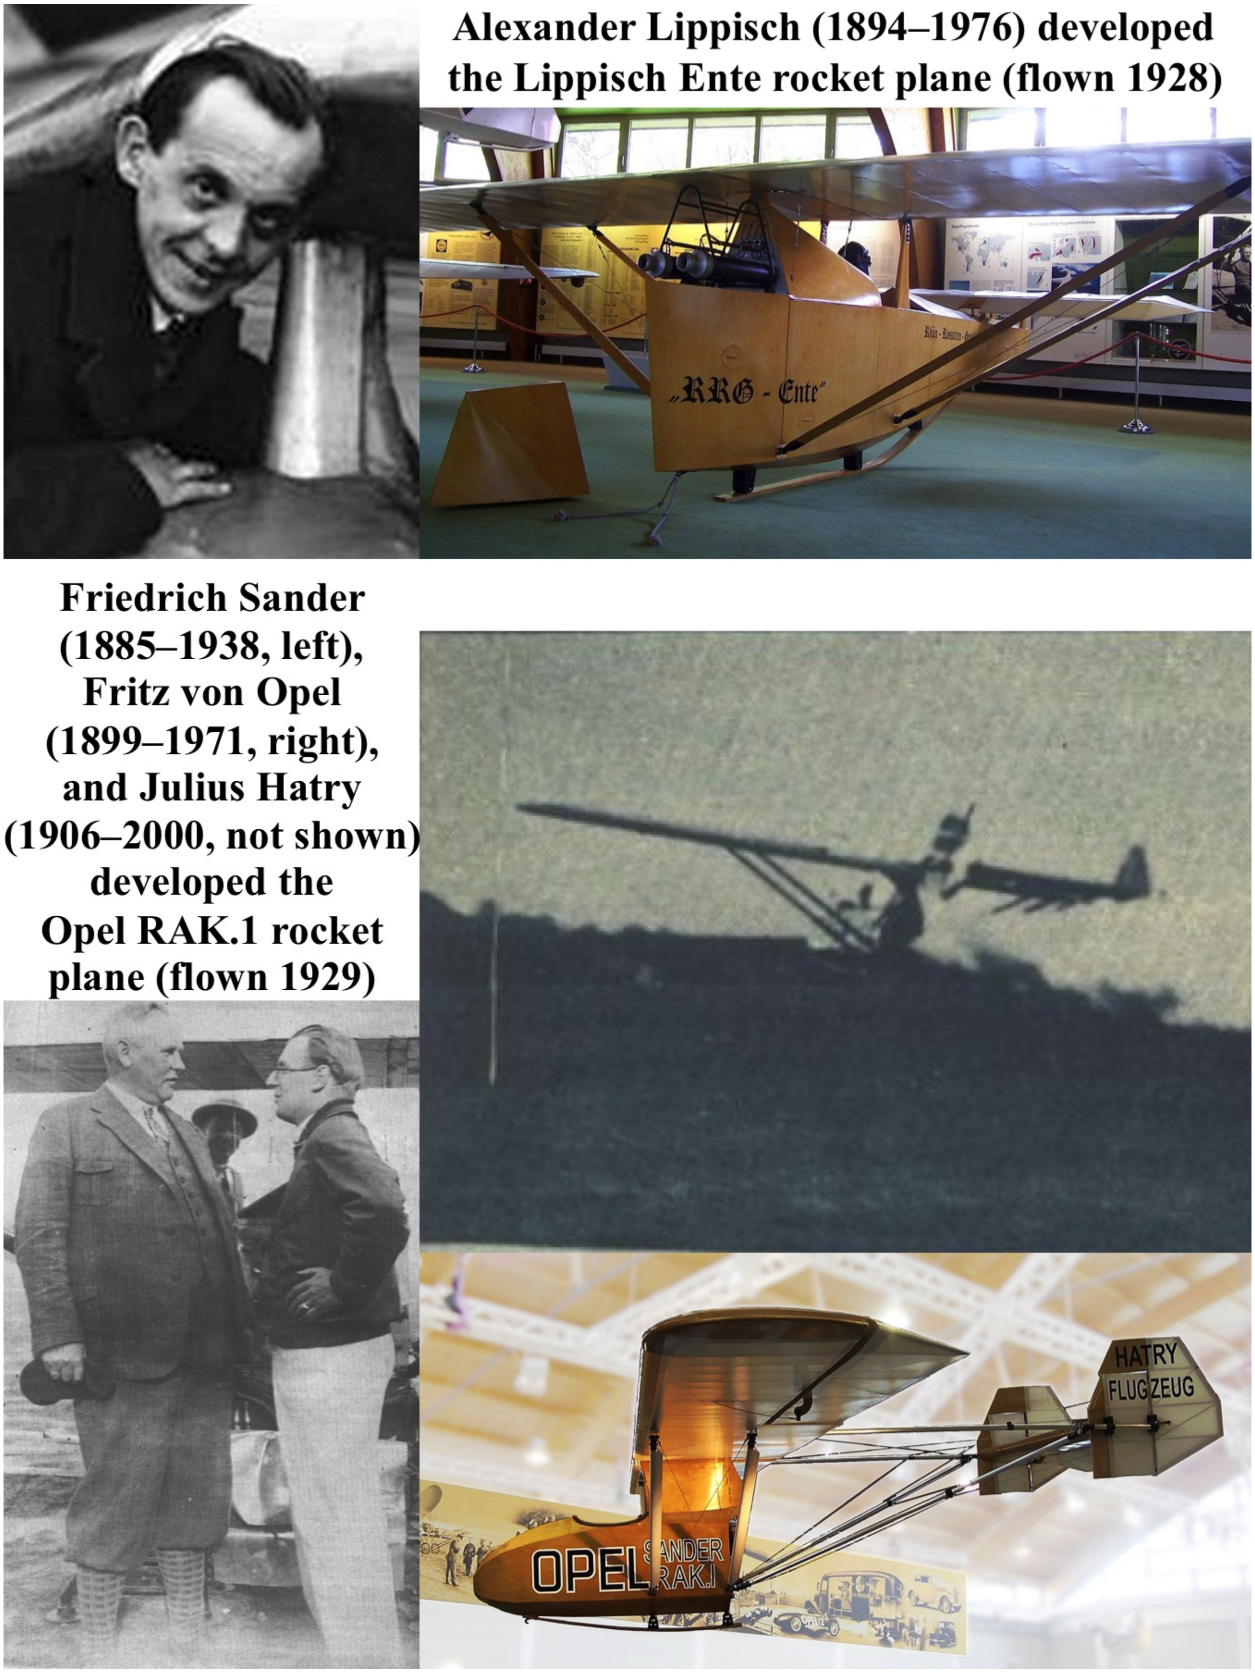
- Kracht also created the DFS 346, which was again designed to be launched from a Do 217 bomber but would then have used its streamlined design and its Walter rocket engine to break the sound barrier. A prototype was constructed but not tested before the end of the war. Captured designs for the DFS 346 appear to have had a tremendous influence on the designs for the Bell X-1 and X-1A through X-1E rocket planes that were built and tested in the U.S. after the war. See Fig. 9.218.

- Alexander Lippisch designed and built the DM-1 rocket plane in 1944, and continued to work on the prototype until spring 1945. It was designed for flight at several times the speed of sound, although a suitable propulsion system was not installed before the war ended. (Lippisch considered various propulsion systems, including Walter liquid rocket engines and a ramjet.) Among other influences it exerted, the DM-1 may be regarded as a direct forerunner of lifting bodies that the United States began testing in the 1960s. See Fig. 9.219.

After the war, Lippisch moved to the United States, where he developed a wide range of aerospace technologies at the White Sands Missile Range, Convair, Collins Radio, and his own Lippisch Research Corporation. Walter developed submarines and other technologies in the United Kingdom, United States, and West Germany. Felix Kracht worked on many aerospace projects in France and West Germany, eventually finishing his career as the Senior Vice President of Airbus.



Alexander Lippisch (1894–1976) developed the Lippisch Ente rocket plane (flown 1928)
„RRG - Ente"
Friedrich Sander (1885–1938, left), Fritz von Opel (1899–1971, right), and Julius Hatry (1906–2000, not shown) developed the Opel RAK.1 rocket plane (flown 1929)

Figure 9.219: Alexander Lippisch created the DM-1 rocket plane prototype, which was designed to travel at several times the speed of sound.

9.9.2 Space Planes

As shown in Fig. 9.220, different types of vehicles can employ different trajectories for reentering the earth's atmosphere from space. In a ballistic reentry, the vehicle cannot generate aerodynamic lift to stay aloft, so it quickly plunges into denser and denser layers of atmosphere, rapidly decelerating due to the large aerodynamic drag force. Ballistic reentry trajectories involve decelerations of at least 8–9 times earth's normal gravity, as well as tremendous heating from atmospheric friction. Ballistic reentry is used by most warheads and was used by the Vostok and Mercury space capsules.

In contrast, lifting reentry trajectories apply to the case in which the vehicle generates aerodynamic lift, which allows the decelerating vehicle to remain much higher, in the thinner parts of the atmosphere, much longer than is possible for a ballistic vehicle with no lift. As a result, vehicles using lifting reentry trajectories experience much smaller decelerations and heating loads, which is why space plane designs are especially attractive. They can also maximize the distance travelled, which was of great interest for long-range bombing during World War II.

As shown in Fig. 9.221, Ludwig Roth (German, 1909–1967), with backing from Wernher von Braun and Walter Dornberger (German, 1895–1980), led the team that developed the A-4b or A-9 winged rocket and launched it in 1945. For evidence that versions of the A-9 designed to accommodate two astronauts may have actually been manufactured during the war, see Section E.2.

As illustrated in Fig. 9.222, Eugen Sänger (1905–1964) and Irene Bredt (1911–1983) designed the Silbervogel space plane, which would have accommodated one astronaut and was even larger than the A-9. They made detailed designs and trajectory calculations for the Silbervogel from the 1930s until 1945. For evidence that prototype hardware for the Silbervogel may have actually been constructed during the war, see Section E.3.

If desired, a vehicle can skip off the upper atmosphere like a fast-moving flat rock skipping off the surface of a pond, and this is called a skip reentry (Fig. 9.220). Both the A-9 and Silbervogel would have used rocket power to achieve a suborbital flight, and then could have repeatedly skipped off the atmosphere to travel part of the way around the Earth before reentering for a final time and bombing a target.[22]

Building upon the wartime work on the manned winged A-9 and Silbervogel, many creators and creations from the German-speaking world played critical roles in postwar programs to develop space planes, including the U.S. Space Shuttle:

- Wernher von Braun and other German-speaking engineers published detailed descriptions and illustrations of a space plane in 1952 in *Collier's* magazine, in order to try to excite U.S. public interest and government funding for such a project [*Collier's* 1952-03-22].

---

[22] A more complex reentry trajectory that is closely related to the skip reentry is the double-dip reentry. If a spacecraft is returning from deep space with a huge amount of kinetic energy, its deceleration and aerodynamic heating would be too great if all of its kinetic energy were expended during just one pass into the earth's atmosphere. For this reason, the U.S. Apollo and Soviet Zond capsules that returned from the moon executed a double-dip reentry, making two passes into the atmosphere before landing. The wartime calculations for the A-9 and Silbervogel pioneered this area of reentry trajectory methods, and then German-speaking scientists who went to the United States and Soviet Union after the war helped to implement those methods.

- In 1946, Walter Dornberger began work on the Bell Aerospace GAM-63 RASCAL air-launched cruise missile, a large liquid propellant rocket with wings designed for long-range horizontal flight (p. 1854). In 1952, Dornberger led the Bell Aerospace team that proposed the Bomi (Bomber Missile) space plane, which was heavily based on the wartime Silbervogel designs (p. 1932). In 1954, Dornberger's team designed the X-15 rocket plane, which had many similarities to the wartime manned A-9 designs [Käsmann 2013, p. 105]. After the Bomi proposal was rejected, Dornberger was instrumental in recycling the Bomi and Silbervogel designs to create the X-20 Dyna-Soar space plane; a prototype was built but the program was cancelled in 1963 [Robert Godwin 2003].

- Hans Multhopp (German, 1913–1972, p. 1705) designed the Martin Marietta X-24 lifting body, which first flew in 1969 [R. Dale Reed 1997, pp. 129–130, 136]; see pp. 1933 and 5612.

- In 1965, Walter Dornberger named the newest U.S. space plane program the "Space Shuttle" [Dornberger 1965a, 1965b].

- The U.S. Space Shuttle (Fig. 9.225) incorporated design features, experience, and personnel from the earlier A-9, Silbervogel, Bomi, Dyna-Soar, and X-24 space plane programs [Frank Winter 1990, pp. 42–44, 113–122]; see pp. 5608 and 5610.

- Adolf Busemann (German, 1901–1986) suggested ceramic tiles for thermal insulation on the Space Shuttle, and also contributed his detailed knowledge of hypersonic aerodynamics and heating for the design and reentry [NYT 1986-11-05]; see p. 5611.

- Krafft Ehricke (German, 1917–1984) was deeply involved in space plane projects from Bomi to the Space Shuttle [Freeman 2008].

- The Space Shuttle Main Engines (SSMEs) were directly derived from engine designs with especially high combustion chamber pressures that were developed during and after the war (such as the MBB P111 engine and the Rocketdyne HG-3 engine) by Klaus von Riedel, Karl Stöckel, Hans Georg Paul, Dieter Huzel, and other German-speaking engineers (see pp. 5613–5617).

- The Space Shuttle Solid Rocket Boosters (SRBs) were based on enormous German-speaking contributions to solid propellant rockets (see Sections 9.8 and E.4).

Thus the Silbervogel and the manned winged A-9, as well as the German-speaking scientists who worked on them, led directly to postwar space plane programs such as the X-20 Dyna-Soar, the U.S. Space Shuttle (first launched in 1981, Fig. 9.225), the Soviet Buran (first launched in 1988, Fig. 9.227), and other space planes such as Dream Chaser (Fig. 9.228) [Chertok 2005–2012, Vol. 1, pp. 262–265; Frank Winter 1990, pp. 42–44, 113–122].

For more information on wartime and postwar space plane programs, see Section E.3.

Especially note the striking resemblance to Multhopp's X-24 design (p. 1933); it has simply been made larger to accommodate more people.

9.10 Space Exploration

On top of their work on liquid and solid rocket propulsion and space shuttles, German-speaking creators led the way with regard to other aspects of long-term space exploration, including designing:

9.10.1. Interplanetary trajectories

9.10.2. Space stations

9.10.3. Non-chemical rockets

9.10.1 Interplanetary Trajectories

Walter Hohmann (German, 1880–1945) published a detailed textbook of calculations for spacecraft trajectories and orbits in 1925 [Hohmann 1925]. Figures 9.229–9.230 show illustrations from his book for calculations regarding atmospheric reentry, aerobraking, and what are now called Hohmann transfer ellipses—elliptical orbits for transferring from one nearly circular orbit (such as that of a planet) to another (such as that of another planet) with the smallest possible expenditure of energy. The methods that Hohmann proposed and worked out in 1925 have been utilized quite effectively since the 1960s and will continue to be widely used in future space missions.

In 1928, Franz von Hoefft (Austrian, 1882–1954, Fig. 9.231) laid out the first systematic plan for steadily progressing from small initial test rockets to very large rockets capable of carrying people to the moon and to other planets [Ley 1928]. Although von Hoefft did not have the opportunity to realize his vision, Wernher von Braun's team did, with their long series of rockets in Germany in the 1930s and 1940s and then in the United States through the 1960s.

Willy Ley (German, 1906–1969, Fig. 9.231) studied earth science at the University of Berlin but spent the rest of his life promoting rockets and space exploration, writing a large number of highly influential books in that area between 1926 (when he was only 20) and his death in 1969. Ley's activities and his books directly inspired, brought together, and publicized the work of many other scientists and engineers involved with rockets and space exploration.

For information on the contributions of German-speaking scientists to planetary science and astrophysics, see Sections 4.5–4.6.

Figure 9.231: In 1928, Franz von Hoefft published papers describing a planned series of rockets ranging from small test rockets to large rockets capable of carrying people to the moon and to other planets. Between 1926 and his death in 1969, Willy Ley published a large number of popular books advocating for rockets and space exploration.

9.10.2 Space Stations

German-speaking scientists led the development of space stations from their initial conception through Skylab to the International Space Station.

In 1928, Hermann Potočnik (Austrian/Slovene, 1892–1929), under the pen name of "Hermann Noordung," published a book with detailed designs of a large, circular, rotating space station, as shown in Fig. 9.232 [Noordung 1928]. Potočnik's designs accurately accounted for everything from the solar energy requirements of the space station's power plant to the artificial gravity in its living quarters. He described and correctly calculated a geosynchronous orbit for the space station. Potočnik's book also incorporated many of Hohmann's proposed methods for interplanetary missions. Unfortunately Potočnik died from tuberculosis (which he had contracted during World War I) when he was only 36; if he had lived he might have helped to realize some of his visions.

Guido von Pirquet (Austrian, 1880–1966) and Hermann Oberth (German, 1894–1989) separately designed space stations in 1928 and 1929 [Ley 1928; Oberth 1929]. See Fig. 9.233. Oberth pointed out that such a station could for example tend large space-based mirrors to reflect sunlight on the earth. Depending on they were used, such mirrors might improve everything from agriculture to power production to weather, or they might incinerate opposing countries. Von Pirquet explained in detail how a space station could be used to refuel spacecraft for interplanetary missions.

Krafft Ehricke (German, 1917–1984), one of the later pioneers of space exploration and advanced rocket propulsion (p. 1957), paid credit to these creators who first worked out the mathematical and physical details of space travel [Ehricke 1960, pp. 19–25]:

> In Germany the most theoretical book on space flight, aside from Oberth's book, was written by Walter Hohmann and published in 1925 under the title, *Die Erreichbarkeit der Himmelskörper* (The Accessibility of the Celestial Bodies). It consisted of a systematic treatment of the departure from the Earth, return to the Earth (re-entry), free coasting in space, circumnavigation of other celestial bodies, and landing on these. Hohmann's departure from the Earth was accomplished by means of vertical ascent. Lateral motion, for instance to enter a circular orbit or another cosmic orbit, was to be given after the vehicle had reached its summit point outside the atmosphere. In his discussion of the return to the Earth, Hohmann proposed to use the atmosphere as a brake. [...]
>
> Hohmann was fully aware of the aerodynamic heating problem. He stated that it is important to transform as much of the kinetic energy of the vehicle as possible into vortex motion of the air. [...] For free coasting in space and the circumnavigation of other celestial bodies *transfer ellipses* were considered; Hohmann showed that the *cotangential* ellipse would be the most economical, but would require an increasingly long transfer time when applied to the outer planets of the solar system. He, therefore, also considered "fast" ellipses which intersect the orbit of the target planet at an angle and require, upon arrival, not only a change in scalar velocity, but also in direction. Hohmann was the first to discuss analytically the landing on other celestial bodies, specifically Venus and Mars. However, he believed that the atmospheric conditions on Mars may not be adequate for an exclusively aerodynamic descent, and that retrothrust must be employed. [...]

> Austria contributed two outstanding space flight pioneers of the early 20th century, Guido von Pirquet and Franz von Hoefft. Von Pirquet was the first to investigate systematically the significance of a terrestrial satellite station for interplanetary flight. While Oberth had only mentioned in passing that such satellites could be used as propellant depots, von Pirquet became convinced that, for the realization of space flight with chemical vehicles, refueling on a satellite would be a necessary condition. [...] Although Pirquet's analyses, like Hohmann's, extended as far as to include circumnavigation of Jupiter, his development approach was quite realistic. [...]
>
> Von Hoefft [...] contributed three fundamental thoughts: The balloon-launched, high-altitude rocket; the flat-bottom glide rocket; and the non-aerodynamic configuration of satellite-launched space ships. Von Hoefft visualized eight development steps, each characterized by a particular project. In a sense he is, therefore, the first to present an organic plan for the development of space flight, from a simple balloon-launched sounding rocket RH I to the interstellar vehicle RH VIII. [...]
>
> With this development plan, von Hoefft displayed a remarkable combination of practical sense and vision. Together with his sincere enthusiasm for the cause of space flight, this makes him one of the outstanding pioneers in this field.
>
> In this era of the thinkers, another interesting idea was contributed by H. Noordung. [...] Here Noordung contributed the first engineering concept of such a space station, or rather what he called its "living unit". He introduced the rotating wheel shape in order to provide centrifugal force as a sort of artificial gravity for the crew. [...] He placed his space station into a very high orbit, about 20,000 n. mi. out where it would complete one revolution in 24 hr.
>
> Thus, when the remarkable 1920's drew to a close, the foundations of the new science of rocket flight and astronautics were established.

Plans for a space station and space mirror were seriously considered by the German government during World War II, especially with regard to potential military applications, as illustrated in Fig. 9.234 [NYT 1945-06-29 p. 1, 1945-06-30 p. 3; *Life* 1945-07-23 p. 78; *Time* 1946-09-02 p. 52].

After the war, Hermann Oberth, Wernher von Braun, Willy Ley, and many other German-speaking scientists continued to design and advocate for space stations in the United States [e.g., *Collier's* 1952-03-22]. Figure 9.235 shows a 1952 space station design from von Braun's team, drawn by Chesley Bonestell, based on earlier designs by Potočnik, von Pirquet, and Oberth.

In addition to the large wheel designs, the German-speaking scientists also proposed simpler space station designs as a starting point. Wernher von Braun, Heinz-Hermann Koelle (German, 1925–2011), and others proposed converting the empty upper stage of a Saturn-class rocket into a space station no later than 1959 for the U.S. Army's Project Horizon project. When von Braun's group was transferred from the Army to the recently formed NASA, the project for converting the upper stage of a Saturn V into a space station first became part of NASA's Future Projects Office, then part of the Apollo Applications Program. That project resulted in Skylab, the first U.S. space station, which was launched in 1973 (Figs. 9.236–9.238).[23]

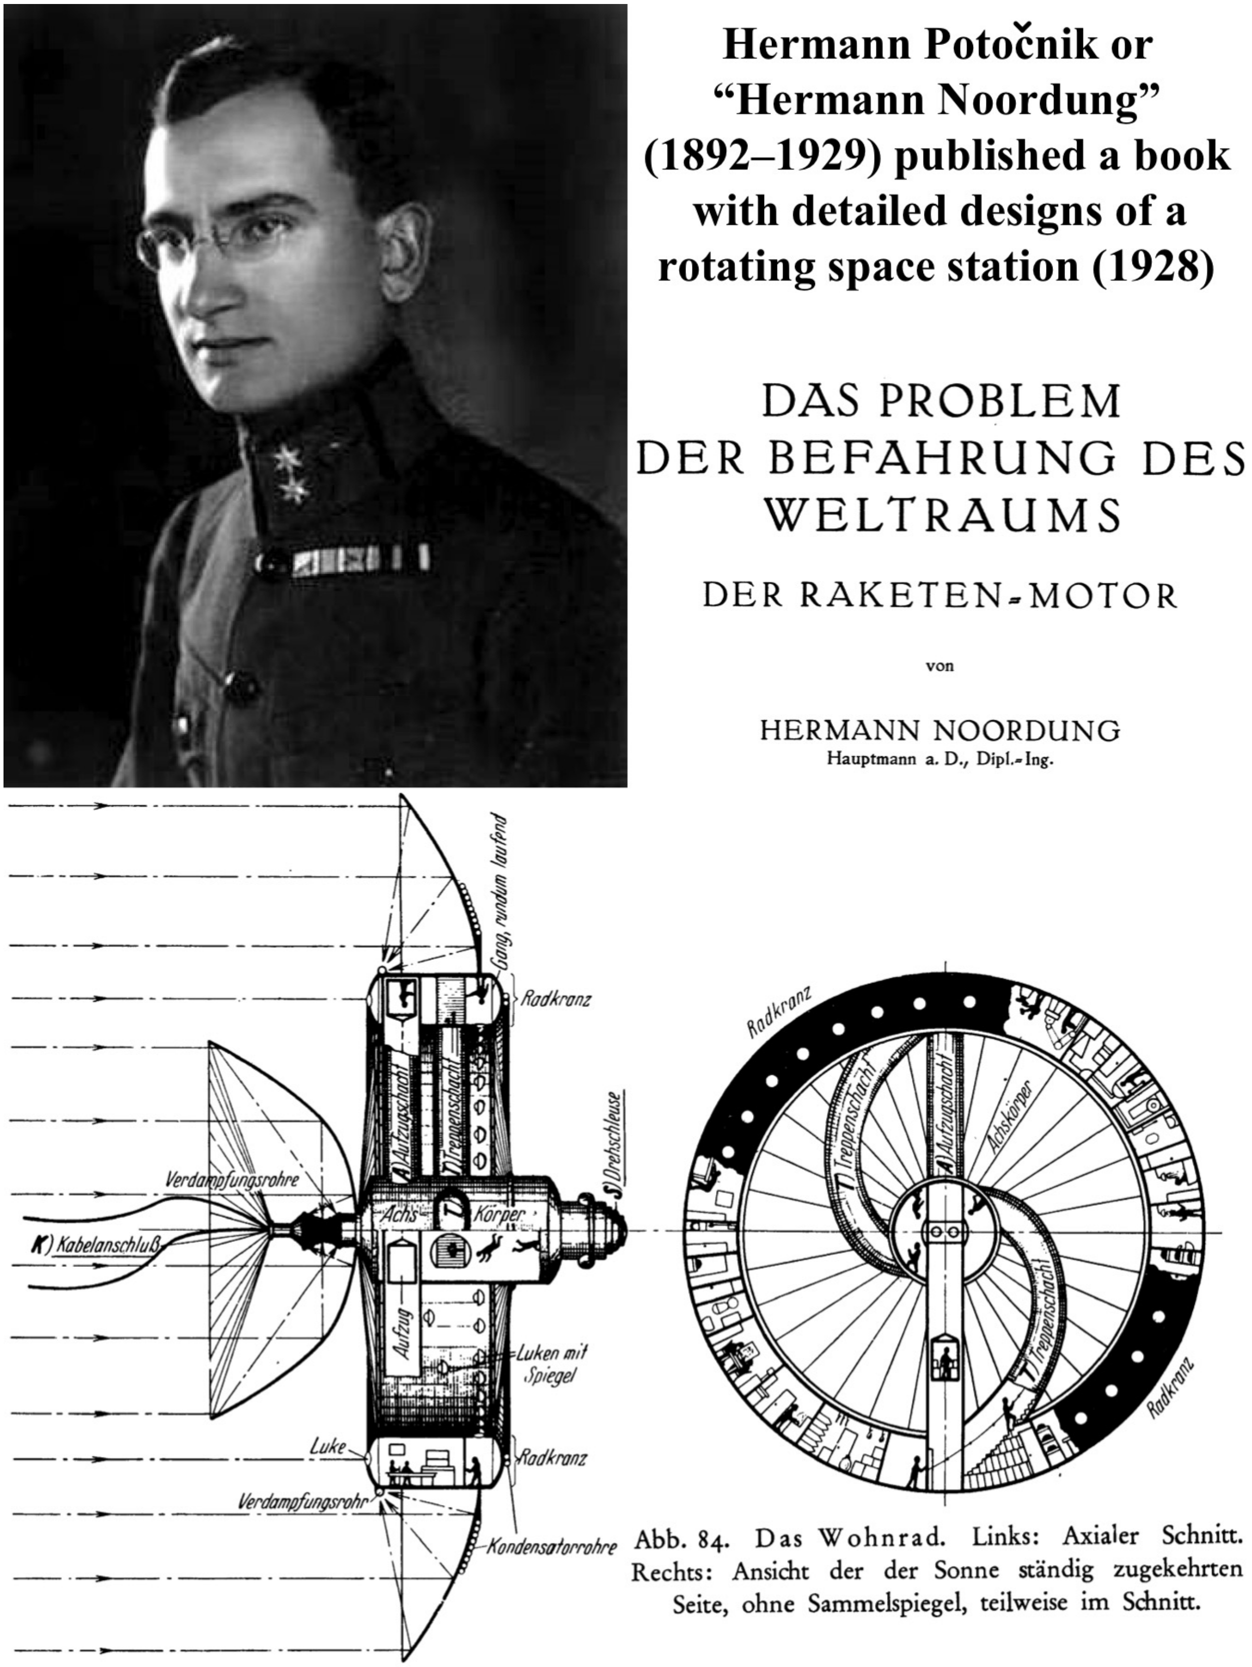
---

[23] Belew 1977; Benson and Compton 1983; Heppenheimer 1997; Michael Neufeld 2007; Newkirk et al. 1977; Shayler et al. 2018; Frank Winter 2019; https://www.nasa.gov/centers/marshall/history/skylab.html

The Skylab design was actually capable of far more than the United States did with it; von Braun's team envisioned it to transport and house astronauts during manned flybys of Venus and Mars in the 1970s [Portree 2012].

Oberth, von Braun, Krafft Ehricke, and other creators also produced many other detailed designs for manned missions to or bases on the moon, Mars, and elsewhere [e.g., von Braun 1991; Freeman 2008]. While those ideas have not been utilized yet, perhaps they will be in the future.

Even the current International Space Station came about largely because of the longtime political advocacy of Hans Mark (Austrian/German, 1929–), one of the sons of the chemist Herman(n) Mark (p. 655) [Hans Mark 1987]. See Fig. 9.239. (Herman Mark's other son, Peter Mark, 1931–1979, conducted important research on electronics at Polaroid and Princeton until his early death.)



Hermann Potočnik or “Hermann Noordung” (1892–1929) published a book with detailed designs of a rotating space station (1928)

9.10.3 Non-Chemical Rockets

Whereas most rockets employ chemical reactions, non-chemical (i.e., nuclear) rockets could deliver much higher performance for deep space missions (Figs. 9.240–9.241). German-speaking scientists began the development of such advanced rocket propulsion systems during World War II and continued to lead their development after the war.

Fission thermal rockets store energy onboard in the form of a relatively conventional fission reactor, which is powered by suitable fuel such as uranium-233, uranium-235, or plutonium-239. Like chemical rockets, fission thermal rockets also store propellant onboard, yet unlike chemical rockets, fission thermal rockets do not require the propellant to undergo chemical reactions and release energy of its own. The propellant is simply heated by the reactor to achieve very high temperatures and pressures, then expelled out of the rocket nozzle, as shown in the upper part of Fig. 9.240. Minimizing the molecular weight of the expelled propellant maximizes the exhaust velocity, so most proposed fission thermal rockets use hydrogen propellant. The temperature to which the propellant is heated is limited by how hot the fission reactor can become without melting the fission fuel or other reactor components, but that still yields an exhaust velocity roughly twice that of the best chemical rocket engine.

The upper part of Fig. 9.242 shows that scientists at Peenemünde and the Reichspost began programs on nuclear rocket propulsion no later than 1942. Manfred von Ardenne (German, 1907–1997), Wernher von Braun, Krafft Ehricke (German, 1917–1984), Werner Heisenberg (1901–1976), Franz Josef Neugebauer (German, 1897–1983), Hans von Ohain (German, 1911–1998), Ernst Stuhlinger (German, 1913–2008), and others worked on fission thermal propulsion during the war (pp. 5757–5773). After the war, von Braun, Ehricke, Neugebauer, Stuhlinger, and others continued to seriously develop fission thermal propulsion in the United States, as shown in Figs. 9.242–9.243.

In contrast to fission thermal propulsion, fission pulse propulsion employs fission reactions that occur outside of the rocket, and therefore are not constrained by the melting temperatures of the fission fuel or any rocket components. Thus the fission reactions can reach the highest possible temperatures—those of a fission explosion. Small fission bombs could be ejected from the rear of the spacecraft; they would explode near the spacecraft, and some fraction of the blast would be intercepted by a thick ablative "pusher plate," transferring momentum while protecting the rest of the spacecraft (Fig. 9.240 bottom). To smooth out the violent shocks of intermittent explosions into more continuous and more survivable acceleration for the spacecraft, the pusher plate would be connected to the rest of the spacecraft by giant compressible shock absorbers. The heat, radiation, and shock to which the vehicle would be subjected pose formidable constraints on the materials and engineering design, yet the prospect of achieving both very high exhaust velocities and high thrust-to-weight ratios with an available energy source (fission explosives) is quite attractive.

Most books on the subject say that nuclear pulse propulsion was first proposed after World War II by Stanislaw Ulam (Polish, 1909–1984), who was a creator from the greater German-speaking world [e.g., Dyson 2002, p. 2]. In fact, this approach was first proposed and explored by even earlier German-speaking creators.

External pulse propulsion by conventional chemical explosives was first proposed by Hermann Ganswindt (German, 1856–1934) [Ron Miller 1993, pp. 75–76; Ron Miller 2016, p. 48].

The sources on p. 5771 show that external pulse propulsion by nuclear explosives was first proposed in approximately 1942 by Wernher von Braun. Considering the German military's great wartime interest in and funding for rockets, nuclear weapons, and revolutionary methods of delivering heavy payloads long distances, it seems likely that fission pulse propulsion was seriously considered during the war, although little relevant documentation is currently available to the public. By the end of the war, work in this area had apparently progressed at least as far as creating small test models powered by conventional chemical explosives, which is as far as the postwar work ever progressed in the United States before the U.S. program was cancelled.

Electric rocket propulsion, or an ion-electron thruster, uses energy (heat, electric voltage, resonant electromagnetic waves, high-energy electrons from an electron gun, or other methods) to ionize initially electrically neutral propellant atoms into positively charged ions and negatively charged electrons, as shown in the upper half of Fig. 9.241. The positively charged ions are accelerated by the voltage difference between two electrically charged grids and ejected from the rear of the spacecraft at some desired velocity. To prevent the spacecraft from accumulating more and more net negative electric charge (as a result of the lost ions) that would actually draw the ejected ions back to the spacecraft, electrons that have been stripped off the ions must also be ejected, generally by harvesting them from the ionization chamber and firing them from electron guns toward the departing ion exhaust. This method of particle acceleration can produce much higher exhaust velocities than chemical combustion or even fission thermal rockets. However, because charged particle beams have far lower densities than flows of more traditional rocket propellant, their thrust is very low. Thus electric propulsion is best for deep space missions where a low thrust applied over the course of months or even years can yield useful final velocities or changes in the spacecraft's orbit. Although ion-electron thrusters could be powered by solar panels or any other source of electrical energy, it is usually proposed to power them with a fission reactor.

Electric rocket propulsion systems were first proposed by Hermann Oberth in 1929 (p. 5772). Experimental development of electric propulsion in Germany began no later than 1937 and continued until at least 1944 (p. 5311). Ernst Stuhlinger, Wernher von Braun, and other German-speaking scientists continued to develop and promote electric propulsion after the war (pp. 1958, 5772). Currently very few documents on the wartime electric propulsion program are publicly available, but it seems likely that Oberth, Stuhlinger, and von Braun were involved in it as well.

Antimatter rockets, first proposed by Eugen Sänger, would store matter and antimatter propellant, then carefully combine them to create very high-energy exhaust (Figs. 9.241 and 9.243). For equal amounts of matter and antimatter, 100% of the combined propellant mass could be converted to energy, versus $< 1\%$ for nuclear reactions, so antimatter propulsion could yield the maximum performance obtainable from a rocket, with exhaust velocities approaching the speed of light. For maximum density, the antimatter could be stored as anti-atoms such as anti-hydrogen (an antiproton plus a positron, or antimatter electron), safely isolated from any matter by electric and/or magnetic fields. Annihilation of an antiproton with a proton creates $\sim 2/3$ charged and $\sim 1/3$ uncharged pions; the charged pions can be directed out a magnetic nozzle before they decay into gamma rays, although the neutral pions would be nearly impossible to direct.

Chapter 10

Creating the Creators

Gaben, wer hätte sie nicht?	Gifts, who is without them?
Talente—Spielzeug für Kinder.	Talents—mere toys for children.
Erst der Ernst macht den Mann,	Seriousness makes the man,
Erst der Fleiss das Genie.	Application the genius.

Theodor Fontane. 1908. Unter ein Bildnis Adolf Menzels.
Gedichte. Stuttgart/Berlin. p. 325.

Chapters 2–9 and Appendices A–E give an overview of a representative (though certainly not exhaustive) set of revolutionary creators and creations that came out of the predominantly German-speaking research world of the nineteenth and early twentieth centuries. There are many indications that systemic innovation-promoting factors were largely responsible for the production of those creators and creations:

- The German-speaking creators and creations came from a relatively small geographical region within a limited period of time, which should prompt close examination of the systemic practices of that place and time that may have contributed to their success.
- That place and time produced a truly enormous number of revolutionary innovations. In fact, it is difficult to identify as many revolutionary innovations that have been wholly developed by the modern research world (not counting innovations that were made by the earlier German-speaking world but adopted and polished by the modern world).
- The former German-speaking world produced that huge number of revolutionary innovations despite having far fewer researchers than the modern world.
- The earlier German-speaking world produced that large number of revolutionary innovations despite having far less research funding than the modern world.
- The former German-speaking world produced so many revolutionary innovations despite having far less political stability than the modern world. It remained highly productive in spite of forces including German unification, Kaiser Wilhelm II's autocracy, World War I, the financial and political crises of the Weimar period, the savagery of the Third Reich, and the devastation of World War II.

- The earlier German-speaking world was not merely holding its position ahead of international competitors, but rather was actually accelerating further and further ahead of other countries. At the beginning of the nineteenth century, scientific fields were generally dominated by researchers in France, the United Kingdom, and a few other countries, and scientific research projects and science/engineering-based industry in the German-speaking world were scarce or lagged years behind the international competition. German-speaking scientists and engineers seriously entered most fields sometime during the nineteenth century, starting from that position of being far behind. As illustrated by the innovators and innovations in Chapters 2–9 and the appendices, by the end of the nineteenth century, German-speaking scientists were ahead in most fields. By 1945, they had overwhelmingly dominated most fields, contributing most of the major new innovations in each field and running years ahead of their competitors, in many cases by a decade or more (e.g., rockets, chemical synthesis, etc.).

Motivated by the above facts, Section 10.1 first compares the size of the early German-speaking research world to that of the modern U.S. and global innovation systems.

Section 10.2 then identifies several specific factors within the German-speaking world that promoted revolutionary innovation:

10.2.1. Science was socially glorified, from children's activities and amateur science clubs to prestigious jobs and government-lauded scientific heroes.

10.2.2. A century-long steady exponential increase in funding gave scientists, employers, and sponsors much more freedom to pursue higher-risk and/or longer-term research.

10.2.3. Many Ph.D. students were encouraged to propose their own research topics and to pursue them independently.

10.2.4. Scientists received their final degrees nearly a decade earlier in life, and independent research funding up to two decades earlier, than modern scientists do.

10.2.5. Scientists who made major contributions to multiple disciplines, and fraternization among scientists from different disciplines, were much more common than in the modern world.

10.2.6. Instead of peer review, an autocratic yet farsighted scientific management culture of "enlightened despots" granted stable jobs and funding to the most promising creators and creations.

10.2.7. Both scientists and sponsors used a systems analysis approach to focus on the most important problems and the most effective innovations to address those problems.

10.2.8. The lack of natural resources spurred the creation of a wide range of innovative alternatives.

10.2.9. International rivalry (both economic and military) was a powerful driving force for innovation.

10.2.10. German-speaking companies were less afraid of losing their own innovations to each other than of being outstripped by foreign countries, giving them a strong motivation to innovate.

10.2.11. There are also other possible factors that should be investigated by future researchers.

10.1 Comparison of Innovation System Size

Before studying factors that promoted innovation in the German-speaking world, one should first consider the total population of the German-speaking world and the size of its innovation system relative to numbers for the modern world.

10.1.1 Total Population and Scientific Innovators in the German-Speaking World

The population of the German-speaking world was spread among several countries, and those countries, their borders, and their populations changed over time. Table 10.1 gives the populations in millions of people for a few key years.

Country	**1871**	**1900**	**1914**
Austria-Hungary	36.0	45.2	52.5
Germany	41.1	56.4	67.0
Netherlands	3.6	5.1	6.3
Switzerland	2.7	3.3	3.8
TOTAL	**83.4**	**110.0**	**129.6**

Country	**1939**
Austria	6.7
Czechoslovakia	14.8
Germany (within 1937 borders)	69.5
Hungary	9.2
Netherlands	8.8
Poland	34.8
Switzerland	4.2
TOTAL	**148.0**

Table 10.1: Populations (in millions of people) of central European countries that were involved in the German-speaking research world. The 1939 data covers approximately the same geographical area as the data from the earlier years, but some of the country names are different due to the altered borders [Mitchell 1975; https://www.destatis.de; https://www.statistik.at; https://www.cbs.nl; https://www.bfs.admin.ch].

Of course, in some of the countries listed in Table 10.1, only some fraction of the population was actually German-speaking or interacted directly or indirectly with the German-speaking research world. Although the total population was steadily increasing apart from wars, ∼100–130 million people is a good general estimate for the total population of the German-speaking world during the early twentieth century.

Like the postwar U.S. research system, the earlier German-speaking research world was divided into three sectors: academic, corporate, and government laboratories.

1. Many universities had very diverse and advanced research programs, especially those in Berlin, Munich, Göttingen, Vienna, Zurich, Prague, etc.

2. Many German companies maintained very large, very well-funded laboratories where company researchers were encouraged to keep inventing and developing 10–20 years worth of future products for the corporate pipeline. Those companies included the various chemical and pharmaceutical companies that ultimately consolidated into I.G. Farben, electrical companies such as Siemens, AEG, and Telefunken, aerospace companies such as Heinkel and Junkers, etc.

3. Government laboratories included multiple labs run by each branch of the military, various dedicated biology and medical labs, the many different Kaiser Wilhelm Institutes (now called the Max Planck Institutes) in different scientific fields, and even advanced electronics and nuclear laboratories run by the German postal service (Reichspost).

Also like the U.S. system, much of the German-speaking university and corporate research was sponsored by the government, with the rest being funded by companies investing in their own labs and also investing in long-term partnerships with universities and with the Kaiser Wilhelm Institutes.

Good estimates of the total number of people involved in the historical German-speaking research world are difficult to find and depend greatly on the definitions one uses. Some relevant data that can be considered includes:

- Werner Osenberg, head of the planning board of the Reichsforschungsrat (German Research Council), compiled a list of 15,000 significant scientists, engineers, medical research doctors, and technicians during the period 1943–1945 [Jacobsen 2014, p. 41]. (He also listed 1400 research facilities.) Estimates are that ∼15–33% of scientists and engineers fled or were forcibly removed from the German-speaking research world during the Third Reich, primarily due to persecution of those with Jewish ancestry or spouses [Ash and Söllner 1996, p. 7]. This suggests a prewar number of ∼20,000 noteworthy scientists and engineers.

- Over 2000 German-speaking scientists and engineers emigrated to the United States soon after World War II as part of Operation Paperclip and Paperclip-related programs [Linda Hunt 1991, p. 1], over 3000 were employed (willingly or otherwise) by the Soviet Union [Mick 2000], over 1000 by the United Kingdom [Glatt 1994], over 1000 by France [Nouzille and Huwart 1999], and at least many hundreds by other countries [Michael Neufeld 2012]. Adding up those numbers gives a total of at least ∼7,500 scientists who are known to have gone to other countries. Multiplying that number by a factor of ∼2 to account for those who remained in Germany and Austria or who moved to other countries but were not included in the official totals puts this estimate in good agreement with the 15,000 on the Osenberg list. (Indeed, the captured Osenberg list was used by Allied countries in their efforts to recruit German-speaking scientists after the war.) Again factoring in those who fled the Reich gives a rough prewar estimate close to 20,000 scientists and engineers.

- A maximum of approximately 4300 staff worked at German aviation research establishments during World War II [Hirschel et al. 2004, p. 659]. Because aircraft, missiles, and rockets were a large area of focus during the war, that number seems consistent with the above total estimates derived from the Osenberg list and Allied recruiting.

- Deichmann found 445 biologists in Germany, Austria, and the Sudetenland between 1933 and 1945 [Deichmann 1996]. Considering that Deichmann's list omitted many major researchers conducting biology-related research within the Reich (Kurt Blome, Adolf Butenandt, Gerhard Domagk, Eugen Haagen, Heinrich Kliewe, Richard Kuhn, Walter Schreiber, Erich Traub, etc., perhaps because they were medical doctors or chemists conducting biology research, or perhaps because they were part of military research programs) and did not consider German-speaking researchers beyond those geographical regions, the total number of active biology researchers may have been at least twice Deichmann's figure, say perhaps 1000. In view of the number of other fields (chemistry, physics, engineering, etc.) and their popularity relative to biology, the total estimates derived from the Osenberg list and Allied recruiting efforts again seem quite plausible.

- Using the major innovations identified in this book and considering the key innovators behind them (Chapters 2–9 and the appendices), there appear to have been at least ∼2000 especially important German-speaking creators, not all of whom were alive at the same time. This number agrees well with various 1945–1948 Allied lists of key scientists who had been recruited or were targets of recruitment [NARA RG 330 Entry A1-1A].

Based on this data, at a given time in the early twentieth century, the German-speaking world appears to have had no more than ∼2000 creators who were personally making revolutionary discoveries or inventions.

Those creators were part of a system that was approximately a factor of ten times larger and contained ∼20,000 scientists and engineers who at least had documented track records.

(If one were to generously multiply that number by an additional factor of ∼10 to account for all of the people who may have contributed to the system in any fashion from technicians to teaching aides, the total size of the science and engineering world in German-speaking Europe was at most perhaps ∼200,000 people.)

10.1.2 Comparison with the Modern World

Whereas the German-speaking world had a total population of ∼100–130 million people during the early twentieth century, in 2020 the estimated population of the United States was 330 million, and the estimated population of the whole world was 7.7 billion people [www.worldometers.info/world-population]. Thus the earlier German-speaking world had a total population that was ∼1/3 that of the modern United States, and roughly ∼1/70 of the modern global population.

To compare research system sizes, as of 2015 (the most recent year for which fully analyzed statistics are available), there were over 1.3 million people employed in research in the United States, and over 7 million worldwide, as shown on p. 40. (As with the German-speaking world, one might also inflate these modern numbers by a factor of ∼10 to account for all of those people who obtain science or engineering degrees but do not ultimately do research, or who interact with the system in some other fashion.)

Using the estimate of ∼20,000 German-speaking researchers, the early German-speaking scientific world had less than ∼1/65 as many researchers as the modern U.S. innovation system, and less than ∼1/350 as many people as the modern global research system, yet managed to produce the incredible quantity and quality of innovations illustrated by Chapters 2–9 and Appendices A–E.

If modern innovation systems were as effective as the earlier German-speaking innovation system, one would expect them to have produced revolutionary innovations at a rate ∼65–350 times that of the older German-speaking world. Unfortunately they do not appear to have even equalled the output of revolutionary innovations from the earlier German-speaking world (as already noted, not counting innovations that were originally made by the German-speaking world but later adopted and adapted by the modern world).

For this reason, it is of great interest to seek factors that may account for why the German-speaking world was so successful.

10.2 Systemic Factors Promoting Innovation

The objective of this section is to identify and analyze common factors within the German-speaking world that facilitated the success of so many revolutionary scientific creators and creations. As is demonstrated here, there were at least ten different important factors. What all of those factors had in common, though, was that they generally tended to promote greater freedom to pursue longer-term and riskier potential innovations compared to the modern research world.

10.2.1 Cultural Attitudes Toward Science Education and Research

One important factor underlying the scientific innovations from the German-speaking world appears to be cultural attitudes toward education and research that were deeply embedded in German culture throughout the nineteenth and twentieth centuries. Education and research in general, and science and engineering in particular, were highly esteemed, from children's activities and amateur science clubs to prestigious jobs and government-lauded scientific heroes.

The roots of these cultural attitudes can be traced back at least as far as the eighteenth century. While philosophers who were not also scientists are beyond the scope of this book, several German-speaking philosophers played highly influential roles in shaping the intellectual culture of the German-speaking world. In particular, Immanuel Kant (Prussian, 1724–1804), Johann Fichte (German states, 1762–1814), Georg Wilhelm Friedrich Hegel (German states, 1770–1831), and Friedrich Schelling (German states, 1775–1854) placed great emphasis on inquiring into the laws and details of the universe, weighing and even hybridizing alternative explanations to determine the best one (the dialectic, not unlike the scientific method), and finding ways to improve oneself and to help others [Beardsley 1960; EB 2010; Peter Watson 2010].

As discussed later in Section 10.2.5, a number of more scientifically oriented intellectuals applied these same principles to a wide range of fields in science and engineering. Those founding scientific figures included Athanasius Kircher (German states, 1602–1680), Gottfried Leibniz (Saxony, 1646–1716), Leonhard Euler (Swiss, 1707–1783), Johann Wolfgang von Goethe (German states, 1749–1832), and Alexander von Humboldt (Prussian, 1769–1859).

Wilhelm von Humboldt (Prussian, 1767–1835), Alexander's older brother, founded the University of Berlin (now called the Humboldt University of Berlin) in 1811 and is widely credited with developing and promoting the model of universities conducting both education and research in coordination. Drawing upon the earlier work of intellectuals such as those listed above, he articulated ideals that would be characteristic of German-speaking culture throughout the nineteenth and twentieth centuries [Bruford 1975, pp. 13–17, 24]:

> Everyone must seek out his own individuality and purify it, ridding it of the fortuitous features. It will still be individuality, for a portion of the fortuitous is inseparable from the make-up of every individual, and cannot and should not be removed. It is really only in that way that character is possible, and through character greatness.
>
> —
>
> If we imagine a man whose sole aim in life is to cultivate himself, his intellectual activity must finally be concentrated on discovering (a) *a priori*, the ideal of humanity, and (b) *a posteriori*, a clear picture of mankind in reality. When both are as precise and complete

> as possible in his mind, he should, by comparing them, derive from them rules and maxims for action.
>
> —
>
> The true end of man, not that which his transient wishes suggest to him, but that which eternal immutable reason prescribes, is the highest possible development of his powers into a well-proportioned whole. For culture of this kind freedom is the first and indispensable condition.
>
> —
>
> Thus peasants and craftsmen of all kinds could perhaps be developed into artists, that is, into men who loved their particular work for its own sake, improved it through their own initiative and inventiveness and so cultivated their intellectual powers, ennobled their character and refined their pleasures.
>
> —
>
> In general, perhaps the best thing a man can do with his life is to take away with him a living picture of the world, properly unified. For me in particular no task is more suited, more imposed upon me by my nature.
>
> —
>
> He who can say to himself when he dies: 'I have grasped and made into a part of my humanity as much of the world as I could,' that man has reached fulfillment... In the higher sense of the word, he has really lived.

As voiced by Humboldt, these German cultural ideals emphasized (1) individual initiative and creativity, (2) high levels of education and lifelong learning, (3) acquiring and harnessing a comprehensive knowledge of as many fields as possible, and (4) systems analysis to survey everything and then focus on creating solutions for the most important problems.

In Peter Watson's sweeping survey of German intellectual history, *The German Genius,* he explained how these ideals permeated and influenced the German-speaking world [Peter Watson 2010, pp. 53–54, 829–830]:

> There will be a great deal to say about Bildung in this book. Difficult to translate, in essence it refers to the inner development of the individual, a process of fulfillment through education and knowledge, in effect a secular search for perfection, representing progress and refinement both in knowledge and in moral terms, an amalgam of wisdom and self-realization.
>
> [...I]t is clear from what has gone before that Germany was the first country to boast an educated middle class of any size and that this was all important for its emergence as a great power.
>
> A few statistics will underline this. Prussia enforced school attendance for children between the ages of seven and fourteen from the 1820s (in Britain children were not compelled to go to school until 1880) and by the 1890s had two-and-a-half times as many university students in proportion to population as did England. [...I]n Germany, in 1785 there were 1,225 periodicals published, compared with 260 in France. In 1900 Germany had 4,221 newspapers, France roughly 3,000 (and Russia 125). In the early

> nineteenth century, when England had just four universities, Germany had more than fifty. James Bowen, in his three-volume history of Western education, points out that Germany took the lead in the establishment of scientific societies in the early nineteenth century, published the greatest number of journals in the vernacular, and became the leading language of scientific scholarship. In 1900 illiteracy rates in Germany were 0.5 percent; in Britain they were 1 percent and in France 4 percent. By 1913 more books were published annually in Germany (31,051 new titles) than in any other country in the world. [...]
>
> It was the educated middle class that made the exciting advances in scholarship that so attracted academics from abroad (especially from America), that rendered the bureaucracy of the ever-coalescing German state so efficient and creative and led to the groundbreaking scientific achievements of the second half of the nineteenth century, that transformed Germany economically, and on which so much of modern prosperity—not just in Germany—is based. [...]
>
> The development of modern scholarship, the concept of Bildung, and the innovation of the research-based university were seen at the beginning of the nineteenth century as a form of moral progress. Education was not simply the acquisition of knowledge but looked upon as a process of character development during the course of which a person would learn to form critical judgments, make an original creative contribution, *and* learn about his or her place in society with its duties, rights and obligations. Education as Bildung involved a process of *becoming,* a form of secular perfection or salvation that was, for the educated middle class, the very *point* of life in a world between doubt and Darwin.

Throughout the nineteenth and early twentieth centuries, German-speaking universities expanded and became more advanced, and the social status of people who taught at or graduated from the universities increased in parallel. Ulrich Wengenroth, a scientific historian at the Deutsches Museum in Munich, described that social status [Landes et al. 2010, p. 284]:

> At the same time a new source of respect and status emerged. Kaiser Wilhelm, himself a great admirer of science and engineering, very much against the opposition of the traditional universities created the title of “doctor of engineering” for the *Technische Hochschulen* (institutes of technology). This opened new opportunities for ambitious engineers to gain the kind of respect and recognition that had been the privilege of the humanistic elites of the traditional worlds of learning. And it was a watershed; academic titles in engineering and science soon displaced the Kommenzienrat and the Geheimer Kommenzienrat, while the *Honorarprofessor* (honorary professor), which in everyday life often was stripped of its somewhat depreciating prefix *Honorar* to sound like a bona-fide professorship, carried the status of nobility. Whatever the dubiousness of some honorary degrees, the currency of status and vanity had changed. More prestigious universities would look more closely at the validity of reasons to confer academic distinction. The Honorarprofessor, even if a CEO, would have to teach students and often was interested in fostering common research programs in his company and his university. The academization of entrepreneurial prestige through the twentieth century was as much an expression as a strengthening of a knowledge-based approach to managing product development.

The very high social status and high relative pay for scientists and academics in the German-speaking world were apparently deeply ingrained in the culture, so they persisted throughout the political and financial upheavals of the German-speaking world in the nineteenth and twentieth centuries. Hariolf Grupp and his colleagues remarked on how stable the German scientific system was despite these political instabilities [Shavinina 2003, pp. 1038, 1041]:

> Most astonishingly, the German innovation system was very *stable*, although it witnessed several political system changes in the past century. The total amount of government spending on science and innovation followed similar quantitative tracks after its formation in the 19th century, the First World War and after the Second World War. The respective central power was not a strong pillar in science and technology. Contrary, the science and technology operation was maintained and was always reconstructed by the German states before the central power found ways to establish itself as dominating. However, considerable differences are observed when regarding the strong role of enterprises on innovation after the Second World War, which was—in pecuniar terms—not as visible before. Only after reunification in 1990, the acting power was the federal government at a time when enterprises were largely dominating the financing of R&D. This was definitely different hundred years ago.
>
> In terms of the basic sectorial structures in science and technology, the strong and the weak sides were almost the same whatever regime and territorial boundaries existed. This *persistence* of the innovation system points to a *resistant innovation culture* in and around Germany, which may not be influenced too much by external shocks or incentives, be it in monetary or institutional form. [...] Even the isolation of the former GDR and its subjection under the communist regime could not change much.
>
> There seems to be a specific German understanding of the opening and prosecution of technology trajectories. The industrial research system in Germany was one of the first in the world to be formed and developed. Other countries followed that pattern more or less closely. Yet the subjects of research seemed to be different between the countries and remained largely constant over long periods. Obviously the technical and scientific elites in Germany succeeded to follow their interests in any political system collectively. For the research and education policy this means that soft factors like group identity, schools of thought and personal exchange are more reliable and more efficient government instruments than the traditionally monetary incentive systems. This sustainable culture imprint can only be analyzed and detected in historical time series.

Because this reverence for science was so deeply imbedded in the culture of the German-speaking world, children in that world grew up with dreams of making revolutionary scientific discoveries and inventions. In his published dissertation, Peter Fisher gave an overview of some of the science fiction that was popular in the German-speaking world in the early twentieth century [Fisher 1991, pp. 104, 115, 221]:

> “In cities throughout Germany, people eagerly lined up at newspaper kiosks,” recalled Hans Dominik proudly, “in order to buy the latest part of my serial novel in the *Woche*.” [...] An electrical engineer who had turned to journalism and popular science, Dominik and his publisher, the conservative Scherl Verlag, were the undisputed masters in producing and marketing a type of formula fiction which they called the *technischer Zukunftsroman*. [...]

> Dominik was not the only science fiction author who sought to assuage the readers' feelings of hurt national pride by concocting stories of potent German inventors creating and controlling future upheavals. Other highly successful authors of popular fiction like Otfrid von Hanstein, Fritz Mardicke, and Otto Willi Gail, or amateur writers like Paul Thieme, also tried their hand in the still new genre. [...] The political drift of these stories manifested itself in an appeal for the recognition of Germany's achievements and (supposedly) superior culture—as witnessed by remarkable advances in science and technology—and by thinly veiled threats that these could be employed against hostile nations. [...]
>
> Dominik's protagonists, like those in other German science fiction of the 1920s, were constructs of an imagination hopefully awaiting salvation in the form of an engineer-messiah. Lämmel even spoke of a day of "technological liberation" and an age of "technological Bismarcks." The repeated sense of wonder and mystery that surround these saviors was meant to suggest that they were emanations of a divine will, driven forward to right the wrongs of recent history. [...]
>
> The writers' favorite props—atomic energy, ray guns, powerful submarines, and light-metal and giant aircraft—serve to reveal hitherto unattained power, but usually appear more like magic wands than believable inventions. Yet, despite the vague imagery of the new superweapons, it seems that there was a wide measure of belief in the imminent creation of such revolutionary armaments.
>
> [...T]he fictive scientists and engineers strove to create powerful inventions that would "free" the nation. While the rightist dictators tamed the masses, the inventors controlled the equally awesome forces of technology. [...]
>
> The technological successes imagined by Weimar's science fiction authors expressed an ambivalent mood—a desire for the recognition of spiritual and technological greatness, as well as a wish to avoid another world war.

These science fiction stories were wildly popular and were avidly consumed by children and adults throughout Germany. They emphasized individualism and presented fictional role models for how a young engineer or scientist could invent or discover something so important that it would change the fate of the country or of the entire world (Fig. 10.1). Early films depicted similar stories about creating a life-like robot (Fritz Lang and Thea von Harbou's *Metropolis*, 1927), building a moon rocket (Lang and von Harbou's *Frau im Mond*, 1929), and accomplishing other technological feats (Fig. 10.2).[1]

At the same time, real-life scientific heroes from Albert Einstein to Fritz Haber were lauded by the media and the government (Fig. 10.3). Amateur science societies such as the Society for Space Travel (Verein für Raumschiffahrt) allowed children and adults to conduct their own research and development projects (Fig. 10.4).

It would be difficult to overestimate the importance of all of these fictional and real role models in shaping the interests and individuality of young future scientists and engineers.

10.2.2 Funding Levels

The amount of funding committed to scientific research obviously has a large effect on the quantity and quality of the resulting work. Data for total public expenditures for science in Germany during the period 1860–1938, converted into inflation-adjusted values (millions of 1913 Reichsmarks), is readily available and summarized in Table 10.2 [Nelson 1993, p. 125].

Year	**Annual budget (millions of marks)**	**Inflation-adjusted (millions of 1913 marks)**	**% of gross domestic product**
1860	6.0	10.7	0.06
1870	10.5	14.7	0.08
1880	27.3	33.6	0.16
1890	32.7	37.4	0.14
1900	53.2	59.9	0.16
1910	91.2	94.8	0.20
1913	101.9	101.9	0.19
1925	282.9	206.8	0.42
1930	359.6	241.3	0.55
1938	513.4	446.6	0.52

Table 10.2: Total public expenditures for science in Germany during the period 1860–1938.

There does not appear to be good data on German industrial research spending during that time. Hariolf Grupp and colleagues summarized this problem [Shavinina 2003, pp. 1021, 1029]:

> Pfetsch undertook adding up scientific expenditure between 1850 and 1975, so that rough estimates about the degree of R&D financing can be derived from this; however, these data records only include *public* expenditure, disregarding the private sector. Consequently, industrial innovation indicators must be researched separately. [...]
>
> It is still difficult to prove the companies' increasing R&D expenditure for such an undeniable success. In particular, no complete data records are available about monetary expenditure or research personnel prior to the end of the Second World War, i.e. the data record established by Pfetsch regarding public scientific expenditure has no counterpart for industry. Today's statistics about R&D expenditure and personnel of the Federal Republic systematically start from the year 1962; certain presumptions allow the reconstruction of the corresponding indicators starting from 1948/1949 [...]

Despite the absence of comprehensive pre-1945 industrial spending data, postwar data shows that during the period 1950–2000, the percentage of total German research expenditures coming from industry instead of government varied between 40% and 60% [Grupp 2002, p. 13], or in other words industrial research spending was roughly equal to government research spending for at least half a century after the war. In the absence of rigorous pre-1945 data, it seems plausible to assume that industrial research spending was also roughly equivalent to government research spending during this period, and that trends in government funding were indicative of trends in total scientific funding.

Similarly, pre-1945 funding data for other geographical regions of the German-speaking world is difficult to find. Nonetheless, it seems reasonable to assume that funding in other German-speaking areas either followed the same trends as the funding in Germany or else was significantly smaller than the German funding. In either case, the rate of increase for German government funding would be a good indicator for the rate of increase for funding for the entire German-speaking research world.

Based on the above data, Fig. 10.5 shows a semilogarithmic plot of total public science funding in Germany from 1860 to 1938 (plotting the data points from Table 10.2 as red circles, measured in inflation-adjusted millions of 1913 marks). Over this 78-year period, funding increased by a factor of 41.7 (red dotted line), equivalent to doubling every 14.5 years on average, or to increasing by a factor of 6.8 over a typical full scientific career of 40 years.

Although the data in Table 10.2 only begins in 1860, German research had been steadily increasing since around 1800, as illustrated by the numerous examples in Chapters 2–9. Likewise, although the data in Table 10.2 ends in 1938, World War II spurred further increases in R&D, as shown by the examples in Appendices A–E. Thus the exponential trend in funding seems to have persisted for at least a full century, and likely more like a century and a half.

Figure 10.6 plots the same data on total public science funding in Germany from 1860 to 1938 from Table 10.2, but instead shown as a percent of gross domestic product (GDP).

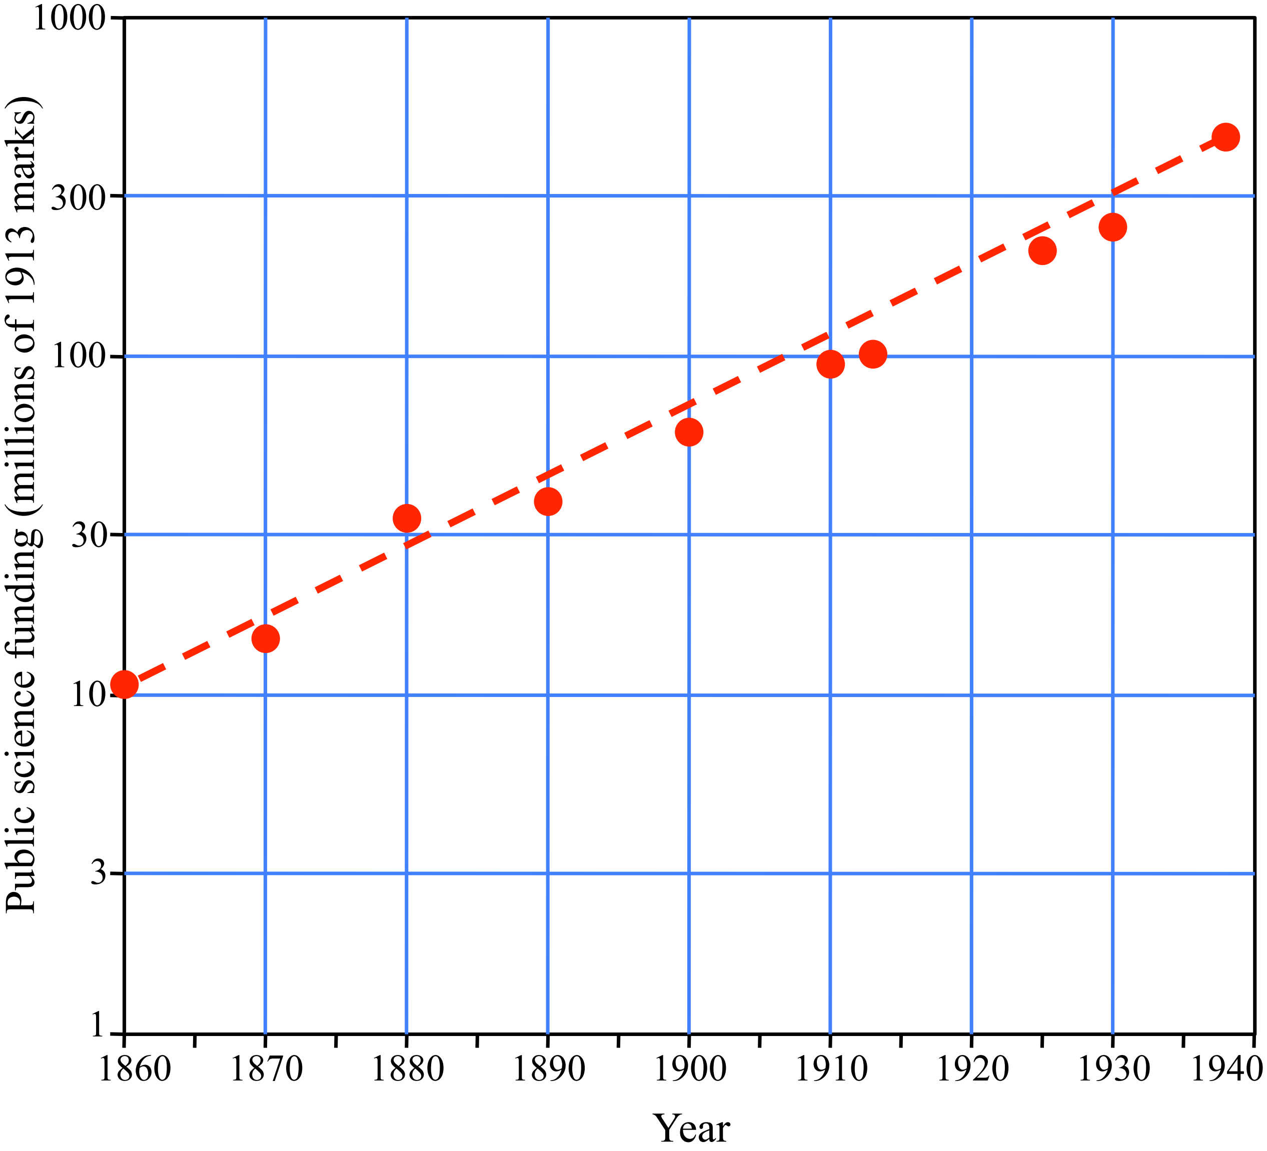

Figure 10.5: Semilogarithmic plot of total public science funding in Germany from 1860 to 1938 (data points as red circles, measured in inflation-adjusted millions of 1913 marks). Over this 78-year period, funding increased by a factor of 41.7 (red dotted line), equivalent to doubling every 14.5 years on average, or to increasing by a factor of 6.8 over a typical career of 40 years.

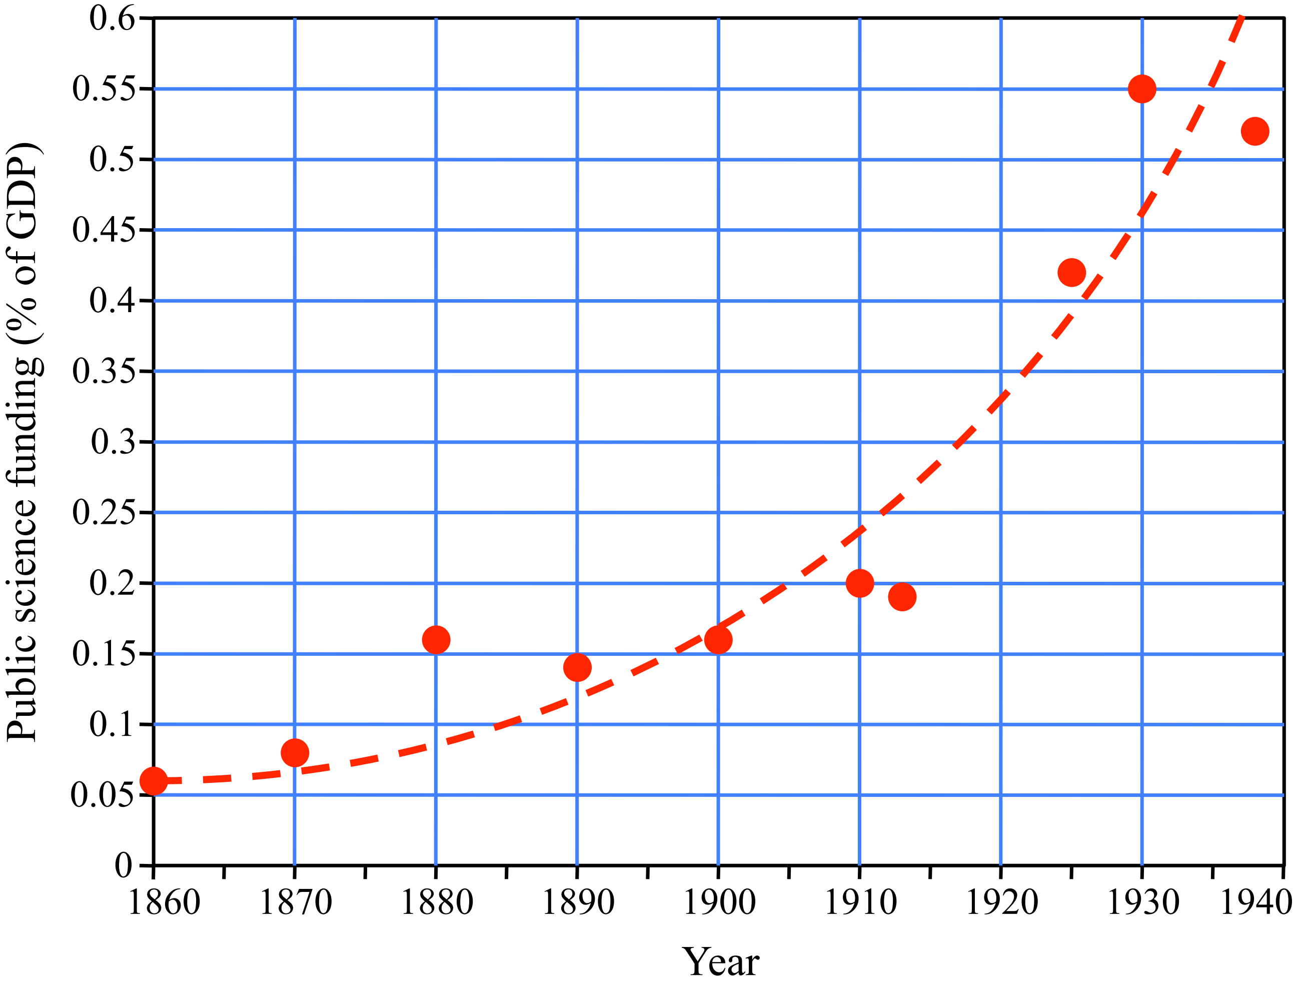

Figure 10.6: Total public science funding in Germany from 1860 to 1938 as a percent of gross domestic product (data points as red circles, extrapolated trend as red dotted line).

In addition to the obvious effect of increased spending resulting in increased research during this more than a century-long period of exponential growth in the German research world, there are less obvious yet critical effects:

- Modern funding levels are nearly flat, and effectively long-term career positions only become available as the people currently holding them retire or die, creating ferocious competition among far too many science graduates for far too few jobs, research grants, and publication slots in high-profile journals. In contrast, because the total funding in the older German-speaking system steadily increased by a factor of 6.8 over typical career times of 40 years, roughly 6.8 times as many graduating students were able to find good jobs in the research system as would have been possible with flat funding levels (assuming that the cost per scientist remained approximately constant). In fact, since some graduating students could find jobs as the German-speaking research world expanded outside Germany, and many graduating students found jobs by emigrating to the United States, United Kingdom, and other countries, the number of graduating students able to find good jobs was significantly higher. The wars in the nineteenth and twentieth centuries also culled a significant percentage of the population. Thus the number of graduating students able to find good research jobs may have been effectively ~ 15 times or more higher for the historical German-speaking world than for the modern research world.

- Greatly increasing the amount of funding and jobs greatly lowered the age at which newly graduated researchers could pursue their own independent research, giving them more years to produce innovations, especially more years when they were young, full of energy, very creative, and less weighed down by family and professional obligations.

- Greatly increasing the amount of funding and jobs greatly reduced the amount of time and energy that researchers had to devote to pursuing funding and jobs, and greatly increased the amount of time and energy that they could devote to conducting actual research.

- Greatly increasing the amount of funding and jobs greatly reduced the pressure both on the researchers and on those responsible for selecting which researchers to support. Reducing that pressure made it much more acceptable for researchers to pursue longer-term work without an immediately demonstrable payoff, as well as more innovative higher-risk work that was less guaranteed to yield results than very incremental, low-risk work. When slots for new researchers were plentiful, it was much easier for employers and sponsors to gamble that some of them would ultimately pay off and some would not.

10.2.3 Mentoring Style

Many creators who were educated in the German-speaking world described the mentorship that they received from their doctoral dissertation advisors. Although there was considerable variation, and not all had a positive experience, a great number of the creators described a style of mentoring that was very different than that typically experienced by Ph.D. students in the modern U.S. system:

- In the German-speaking world, many doctoral advisors (not all, but many) encouraged and supported their students to independently propose and pursue their own research topics and methods. In fact, students were praised and evaluated specifically on how independently they had acted in finding a dissertation topic and carrying out their research on it. In contrast, students in the modern U.S. system are generally expected to work on a specific dissertation topic assigned by their advisor, using the specific methods and materials provided by their advisor, a process which neither teaches nor rewards creativity in young scientists.

- Doctoral advisors in the German-speaking world typically did not claim credit for their students' research. They usually allowed their students to publish or patent the resulting research discoveries by themselves, without adding the doctoral advisor's name to the publication or patent. That was very different than the modern U.S. system, where every resulting publication or patent bears the advisor's name as the authoritative final author, even if the advisor made no real contribution to the actual scientific discovery.

- In the German-speaking world, doctoral advisors generally did not use students as cogs in their own machine. Advisors were expected to serve their students by teaching them, mentoring them, and allowing them to pursue their own independent research. In the modern U.S. system, students typically serve their advisor by carrying out work essential for the advisor's own project, by publishing papers featuring the advisor's name to build up the advisor's reputation, and by helping the advisor to write grant proposals, teach classes, or do anything else requested by the advisor.

- Doctoral advisors in the German-speaking world usually were personally carrying out their own research projects. In laboratories and symposia, various mentors and students were constantly rubbing shoulders as fellow researchers. Such a rich environment provided excellent role models for the students, promoted independence and creativity, and facilitated cross-pollination of ideas among all of the mentors and students. In contrast, doctoral advisors in the modern U.S. system generally spend most of their time writing research grant proposals and issuing orders to their students to carry out specific tasks for those research grants. That modern approach does not give the students good role models for research, does not cultivate independence and creativity, and does not allow many inspiring interactions among all of the mentors and students at the university.

As just a few examples of this mentorship style, the doctoral dissertation experiences of some German-speaking creators are given on the following pages.

Leo Szilard explained that students could either propose their own doctoral dissertation topic or ask their advisor to suggest a topic; Szilard asked his advisor Max von Laue for a topic, but ended up coming up with his own original idea and pursuing that [Weart and Szilard 1978, pp. 9–11]:

> A student of physics had great freedom in those days in Berlin. Boys left high school when they were eighteen years old. They were admitted at the University without any examinations. There were no examinations to pass for four years, during which time the student could study whatever he was interested in. When he was ready to write a thesis, he either thought of a problem of his own or he asked his professor to propose a problem on which he could work. At the better universities, and Berlin belonged to them, a thesis in order to be acceptable had to be a piece of really original work. If the thesis showed the student to be really able and was accepted, the student had to pass an oral exam.
>
> At some point, rather early, I went to von Laue, who was professor of theoretical physics, and asked him whether he would give me a problem on which I could work to get my doctor's degree... I had this problem [in the theory of relativity] which von Laue gave me, but I couldn't make any headway with it. As a matter of fact, I was not even convinced that this was a problem that could be solved. [...]
>
> I went for long walks and I saw something in the middle of the walk; when I came home I wrote it down; next morning I woke up with a new idea and I went for another walk; this crystallized in my mind and in the evening I wrote it down. There was an onrush of ideas, all more or less connected, which just kept on going until I had the whole theory fully developed. It was a very creative period, in a sense the most creative period in my life, where there was a sustained production of ideas. Within three weeks I had produced a manuscript of something which was really quite original.
>
> [...] I took the manuscript to von Laue. I caught him as he was about to leave his class and I told him that while I had not written the paper which he wanted me to write, I had written something else, and I wondered whether he might be willing to read it and tell me whether this could be used perhaps as my dissertation for the Doctor's degree. He looked somewhat quizzically at me, but he took the manuscript. And next morning, early in the morning, the telephone rang. It was von Laue. He said, "Your manuscript has been accepted as your thesis for the Ph.D. degree."

In 1929, Michael Polanyi articulated the German-speaking system of higher education in science [István Hargittai 2016]:

> In Germany the professors grab the students' hands, if he is supposed to be gifted. They are like art collectors whose obsession is discovering talent. They educated me and gave me a position where I could address myself to my abilities. They gave me everything and demanded nothing of me. They trust that who gets to know the joy of scientific work, will never leave it as long as he lives.

Michael Polanyi also practiced the same approach that he had observed and praised. One of his doctoral students was Eugene Wigner. Wigner gave an especially detailed description of how Polanyi mentored him while allowing him to independently pursue his own ideas of how to apply quantum physics to chemical reactions, even though Polanyi himself was not interested in quantum physics [Szanton 1992, pp. 76–81]:

> And there at the Kaiser Wilhelm Institute worked a man who decisively marked my life: Dr. Michael Polanyi. Few people in this century have done such fine work in as many fields as Polanyi. After László Rátz of the Lutheran gimnázium, Polanyi was my dearest teacher. And he taught me even more than Rátz could, because my mind was far more mature. After Rátz and my parents, Polanyi was my greatest influence as a young man. [...]
>
> But his finest gift was to encourage my work in physics, and this he did with all of his very great heart. In all my life, I have never known anyone who used encouragement as skillfully as Polanyi. He was truly an artist of praise. And this praise was vital to me because it was often missing at the great afternoon physics colloquia.
>
> Because Polanyi was a decade my senior and held a far higher position, it was not quite proper for him to befriend me as he did. But Polanyi cared nothing for formal questions of age and status. That was part of his great sweetness. Polanyi was concerned instead that young men should love science and labor to understand it. He was concerned that he could never fully share his love and the knowledge he had gathered.
>
> Like me, Polanyi enjoyed asking questions outside the realm of basic science: Why is the world divided into separate nations? Why do all nations have governments? How should a man live his life in a world filled with evil? Polanyi even taught me some poetry. He made learning a great pleasure.
>
> Dr. Polanyi and I did not always see eye to eye. Polanyi found quantum theory too mathematical for his liking. I was the only one in his lab deeply interested in it. [...]
>
> Polanyi advised my doctoral dissertation at the hochschule. I chose a topic far from the crystallography of Weisenberg or Herman Mark: chemical reaction rates. I wondered: How do colliding atoms form molecules? We knew that hydrogen and oxygen make water in a container, but how soon? How much depends on pressure and how much on temperature? I pursued such questions with elements far more complex than hydrogen and oxygen.
>
> Polanyi was a wonderful advisor. He understood chemical reaction rates both in theory and practice. He accepted my proposal that angular momentum is quantized and that the atoms collide in a proportion consistent with Planck's constant. This idea is now widely known, but then it was rather brash. And studying chemical reaction rates taught me much about nuclear reaction rates that would be useful in future years. [...]
>
> So Herman Mark was a strong teacher, but Michael Polanyi was really the miraculous one. Polanyi loved to ask the fundamental question: "Where does science begin?" He listened to the thoughts of others on this question, but he also had his own well-crafted answer: "When a body of phenomena shows coherence and regularity."
>
> Polanyi loved and honored the scientific method with great truth and devotion. He managed to keep all of science within his fond gaze and a great deal more besides. What a mentor Michael Polanyi was.

Herbert Fraenkel recounted how John von Neumann produced his own revolutionary doctoral dissertation in mathematics, a work that bore the stamp of genius so clearly that Fraenkel and other professors who did not know von Neumann but read the draft dissertation could "recognize the lion by its claw" (*ex ungue leonem* in Latin) [Macrae 1992, pp. 95–96]:

> Around 1922–23, being then professor at Marburg University, I received from Professor Erhard Schmidt of Berlin a long manuscript of an author unknown to me, Johannes von Neumann, with the title "Die Axiomatisierung der Mengenlehre" [The Axiomatization of Set Theory], this being his eventual doctoral dissertation... I was asked to express my views since it seemed incomprehensible. I don't maintain that I understood everything, but enough to see that this was an outstanding work and to recognise "ex ungue leonem."

Hans von Ohain's doctoral advisor at the University of Göttingen was Robert Pohl, an expert on solid state and optical physics. Ohain was already independently pursuing his own longer-term ideas which would lead to the first jet aircraft, but he needed to pick a doctoral dissertation research topic that could be accomplished within a shorter period of time. That topic, a microphone that used light waves instead of electricity to pick up sound waves, was also independently proposed and pursued by Ohain. Ohain described how Pohl gave him general advice, encouraged him to create innovations that were as revolutionary as possible, and allowed him to pursue his ideas on his own [Conner 2001, p. 17]:
